Access to ubiquitous and high speed internet is fundamentally impacting modern societies worldwide and impacting ways in which individuals, households, and businesses utilize the internet. In the United States, the digital divide is evolving (McHenry et al, 2017). The digital divide has been defined as “the gap between individuals, households, businesses and geographic areas at different socio-economic levels with regard both to their opportunities to access information and communication technologies and to their use of the Internet for a wide

variety of activities (OECD, 2011). The U.S. Department of Commerce National Telecommunications and Information Administration now publishes data not only on internet access but also on internet usage. In the U.S., internet adopters use the internet for myriad purposes – for e-communication (emailing, text messaging, social networking), e-commerce (making purchases online, paying bills online, and others), e-education and e-entertainment (watching podcasts, videos, listening to music), accessing health information online (retrieving health insurance records, interacting with physicians online), to more sophisticated forms of usage such as teleworking and interacting with household devices. Concurrently, attention in the extensive digital divide literature is gradually shifting from understanding and examining aspects of adoption of information and communications technologies (ICTs) to analyzing disparities in use (Sarkar, Pick, and Parrish, 2017) – referred to in the literature as the third-level (usage-, practices-, and application-oriented) digital divide.

In this paper, we examine the antecedents of social media utilization in the counties of the United States. Among person aged 15 years or older, 74.4% of Americans (153.7 million) used the internet for online social networking in November 2017 compared to 70.6% (137.3 million) in July 2015 (NTIA, 2018). This growth in the use of online social networking spanned demographic attributes such as age, gender, race and ethnicity, educational attainment, as well as economic variables such as employment status and family income. The growth in online social networking in the U.S. also spanned population density in urban versus rural areas. While the rate of growth varied (for example, 3.4% increase in online social networking in urban metropolitan areas versus 6.5% in rural areas between July 2015 and November 2017), it is clear that social networking among Americans using popular social media platforms is on the rise.

Given this increasing popularity in utilization of the internet for social networking in the U.S. spanning demographic and socioeconomic attributes of users, as well as their location, this paper examines demographic, socio-economic, governmental, and societal openness influences on social media adoption and utilization in 3,109 counties of the United States. Among social media platforms, we focus on Facebook, Twitter, and LinkedIn. The geographic unit of analysis of this study is U.S. counties. Apart from being the oldest form of government in the United States dating back to the 1600s, county governments administer their own economy, education, justice and public safety, health care, social services, transportation, and other services that directly impact the county residents. In addition, counties are often responsible for implementing a broad array of federal, state, and local programs including digital literacy initiatives. In the digital divide literature focusing on technology adoption and diffusion in the United States, the county has hardly been studied before. In fact, disparities in adoption and diffusion, but not utilization of ICTs in U.S. counties has been systematically addressed in only one prior study (Sarkar, Pick, and Rosales, 2016). Additionally, antecedents of social media usage in the U.S. has not been studied in prior literature.

Overall, our research questions are the following:
(1) What factors impact social media use in U.S. counties?
(2) How does social media use vary geographically across U.S. counties?
(3) What county-level policies regarding social media use stem from the findings of this research?

As internet use for social networking increases as part of broader tapestry of growing use of the internet in the U.S., the potential of social media to bridge demographic, social, economic, and locational disparities in some cases and to exacerbate differences in others remains a topic of

keen interest to researchers, practitioners, and policymakers in many fields. Situated in this context, the development and subsequent validation of a conceptual framework of social media utilization in U.S. counties is the central contribution of this paper. No prior study has examined associations of demographic, socio-economic, governmental influences, along with social capital and societal openness on social media adoption and utilization. Derivation of county-level policies to bridge gaps in internet usage for social networking is another related contribution. A novelty of this work is its spatial analysis of social media utilization patterns in U.S. counties, stemming from locational disparities in usage between urban versus rural users. This paper also represents a directional shift in the digital divide scholarly discourse due to its focus on utilization divide rather than adoption and diffusion divide of the internet in the U.S. This is another novelty of this work.

The remainder of this paper is organized into sections on Literature Review of broader county-level studies focused on the digital divide in the U.S., conceptual model of social media use, regression findings, spatial patterns of social media use, policy implications, limitations, and conclusions.

LITERATURE REVIEW OF SOCIAL MEDIA ADOPTION AND UTILIZATION

Academic work on examining various aspects of social media adoption, diffusion, utilization, and impacts is advancing rapidly. Given the proliferation of social media platforms such as Facebook, YouTube, WhatsApp, Instagram, Twitter, LinkedIn, Weibo, Snapchat to name a few, this is hardly surprising. In the digital divide context though, analysis of adoption, diffusion, and utilization of the internet for social networking and underlying disparities of social media use is largely novel.

Participation in social networking has been examined thorough a variety of lenses. Over the past few years, surveys and studies conducted by the Pew Research Center have shed considerable light on social media adoption and utilization patterns among Americans. A recent study (Pew, 2018) has shown that Facebook continues to remain as the dominant social networking platform in the U.S., followed by YouTube, which has many social elements, but is not recognized as a typical social networking platform. Frequency of use, reciprocity of use, issues related to content-trust and disparities stemming from demographic and socioeconomic differences have been cataloged. Incidentally, the role of gender, age, race/ethnicity, educational attainment, and related demographic attributes and socioeconomic variables such as income and employment, participation in the service sector workforce, and others have been the subject of numerous digital divide studies (Pick and Sarkar, 2015).

Diffusion of user-generated content in social media (Qiu, Tang, and Whinston, 2015) and peer influences on participation in social networking have also been the subject of recent studies (Lee, Qiu, and Whinston, 2016; Pearce and Rice, 2017). Such studies shed light on the important role that social capital has been argued to play in providing both material and skills access to those laggards who either do not have access to ICTs such as the internet or do not possess the skills to participate in online activities (Chen, 2013). In terms of examining peer influence and network formation, the study by Lee et al (2016) is notable since it found evidence of homophily in strategic network formation in a location-based social networking context. Pearce and Rice (2017) considered the tension between the digital divide nature and the capital-enhancing nature of social networking sites. Using a nationally representative sample of Armenian adults, this study found evidence of a digital divide between users and non-users of social networking, a modest divide between users of two primary social networking sites used

by Armenians – Facebook and an indigenous Armenian social networking platform, and a slight divide between engagement in capital-enhancing activities on the two primary social networking sites. Both studies (Lee et al., 2016; Pearce and Rice, 2017), recent Pew reports (Pew, 2018), as well as prior digital divide literature (discussed in Pick and Sarkar, 2015) are relevant and instructive and inform the inclusion of correlates of social media usage in the conceptual model of social media usage discussed in the next section.

County- or provincial-level studies of the digital divides in the United States are relatively rare, often due to the lack of reliable ICT adoption, diffusion, and usage data at such geographic unit of analysis. In a prior study examining correlates of ICT adoption in U.S. states, Pick, Sarkar, and Johnson (2015) found that social capital, education, societal openness, urbanization, and ethnicities are significantly associated with ICT utilization. Facebook and Twitter users per capita – two key dependent variables in the study were however found to be not associated with urbanization but positively associated with per capita immigrant population – indicating likely contagion spurred by social contact within respective immigrant communities. Pick and Azari (2005) analyzed socioeconomic influences on technological levels for 164 counties in the United States. While social media adoption or use was not among the study's ICT dependent variables, it revealed that important correlates of technology sectors are professional/scientific/technical services workforce, other services workforce, household income, federal grant funds, college education, and ethnicity. A handful of prior studies have examined citizen engagement via e-government portals of U.S. counties (Huang, 2006, 2007; Manoharan, 2012). Broadband and high-speed internet digital divides in U.S. counties have been the subject of reports of the U.S. federal government (The White House, 2015). Internet diffusion in U.S. counties has been examined through a socioeconomic and geographic lens by Khatiwada and Pigg (2015) using a large sample of 3,000 U.S. counties; yet this study does not include social media adoption or use variables. Overall, the digital divide of internet use for social networking at the provincial level is absent in prior literature. This is the first systematic attempt to examine the influences of demographic, socio-economic, social capital, employment, and innovation on social media utilization in U.S. counties. The study is further enriched by geographic analysis of spatial patterns of social media usage; this provides vital clues about discrepancies in social media usage between demographically and socio-economically diverse metropolitan, micropolitan, and rural U.S. counties.

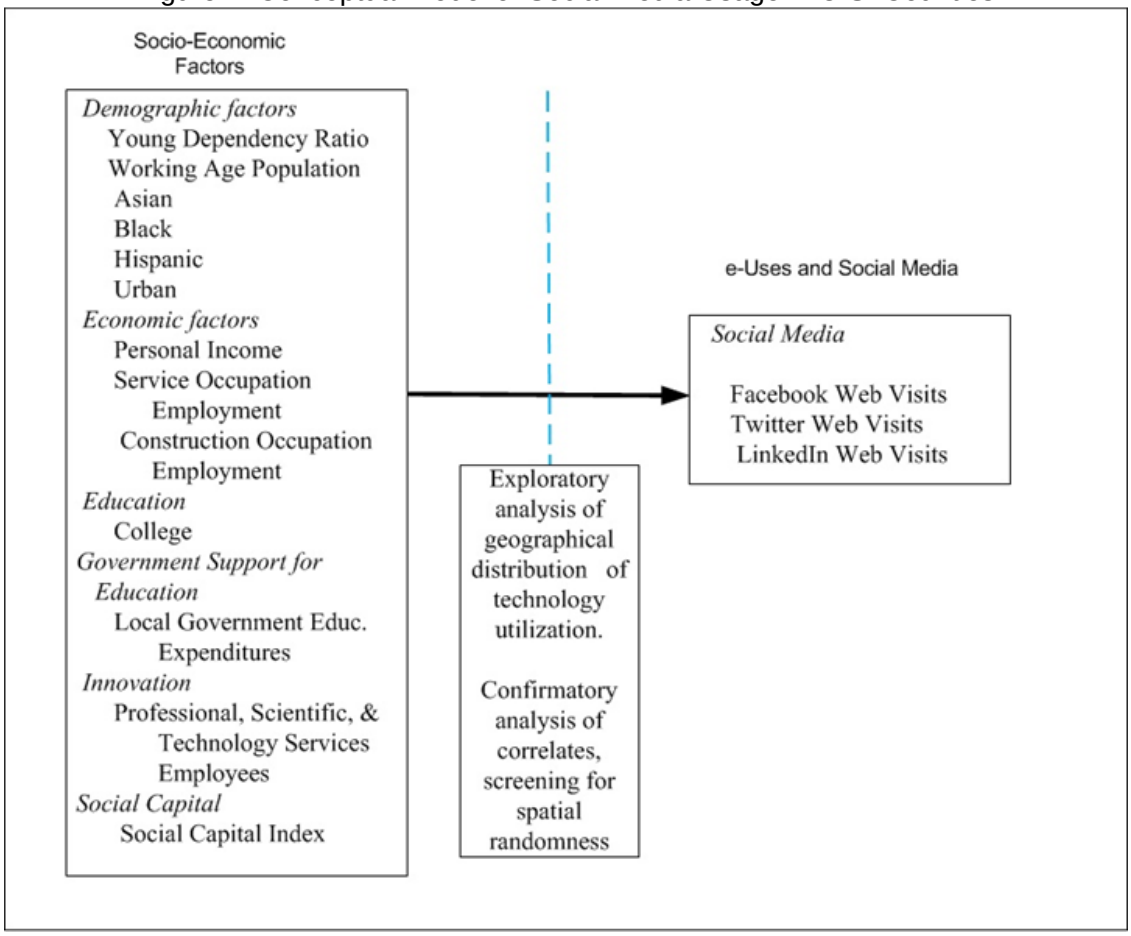
CONCEPTUAL MODEL OF SOCIAL MEDIA USE

The paper's conceptual model is drawn from the Spatially Aware Technology Utilization Model (SATUM), which is appropriate for research on composite influences of various social, economic, and political determinants on ICTs, which can include social media variables. SATUM is based on a large literature of studies, mostly of nations, but also of states, provinces, prefectures, and EU economic units (Nishida, Pick, and Sarkar, 2015; Pick, Sarkar, and Johnson, 2015; Pick and Sarkar, 2015; Vicente and Lopez, 2011). SATUM also has spatial relationships as components, so a research study can assess the extent of spatial bias in multivariate statistical analysis and can perform spatial cluster analysis and other spatial techniques (Farkas et al., 2017). The present study's SATUM-based model is depicted in Figure 1.

Demographic influences: Prior studies have documented an urban-rural differential for ICT utilization. NTIA provided evidence of such a differential for households using broadband in the home; rural households were found to trail their urban counterparts by 10 percent in 2010 (NTIA, 2011). It has been reasoned that more populous, wealthy urban regions in metropolitan

areas with higher levels of educational attainment and higher median home values are more likely to have greater demand for broadband services. We posit that percent of urban population is associated social media utilization in US counties. Evidence of significant disparities in broadband usage at home by different racial/ethnic groups has also been documented; in 2010, Whites and Asians led Black and Hispanic households in broadband use by at least 18 percent (NTIA, 2011). Due to the disparity in internet access due to race and ethnicity we propose that race and ethnicity are associated with technology utilization in US counties; for Asians the association is posited as positive, and for Blacks and Hispanics the association is posited as negative.

Figure 1. Conceptual Model of Social Media Usage in U.S. Counties



Economic influences: Economic factors such as income, integration in the global economy, international trade openness, R&D, degree of economic openness, and GDP have been widely cited to influence ICT diffusion and utilization. Unemployed Americans, aged 16 years or older lag their employed counterparts in broadband usage by more than 10 percent in 2010 (NTIA, 2011). Income-based adoption disparity among individuals in the US for broadband has been documented: in households with annual income of $75,000 or more, 97 percent of individuals used the Internet, compared to 72 percent in households with $30,000 or less income (Perrin and Duggan, 2015). Hence, we posit that personal income per capita is associated with social media use in US counties. Construction costs, specifically installation and maintenance costs were found to be associated with the probability of cell tower location for a spatial econometric

study of cell phone coverage in sub-Saharan Africa. We argue that in the US, the construction sector will impact the physical and infrastructural aspects of ICT development. Therefore, we posit that services sector employment, and construction sector employment are associated with technology utilization in US counties.

Education influences: There is widespread evidence of the influence of education on ICT access and utilization. While adults with at least a Bachelor's degree are very likely to use broadband internet at home (almost 85 percent in 2010), the level of utilization drops rapidly to slightly more than 50 percent for individuals with a high school diploma (NTIA, 2011). In 2013, 93 percent of college graduates used the Internet, versus 50 percent for less than high school education (Perrin and Duggan, 2015). Other education correlates such as level of educational attainment, enrollments in tertiary education, and expenditures per student have been found to be significantly associated with internet use, broadband access, and personal computer use. Accordingly, we posit that college graduation is associated social media use. Government spending on education has been found to be associated with PCs, ICT expenditure, and ICT infrastructure quality (Author, 2008). Therefore, we also posit that local government education expense is associated with social media use.

Innovation influences: Innovation has impacted ICT utilization in some prior research. It can lead to more appealing and productive technology devices and services that increase usage. For instance, as social media capabilities and ease of use have improved through innovation, more users have tended to adopt it. In one study of the uses of several types of technologies for a worldwide sample of nations, innovation measured by scientific articles per capita was the most important independent variable (Author, 2008). Its importance has also been shown for in Asian nations (Quibria et al. 2003). Professional, scientific, and technical services workforce has been found to be significantly associated with receipts and payroll in three technology sectors (Author, 2005). The rationale was such a services sector is comprised of scientists, engineers, medical and health professionals, university researchers, lawyers and attorneys, who are naturally inclined towards innovative technology and are likely to be consumers of ICTs for research and development purposes. Accordingly, we propose that professional, technical, and scientific services employees per capita, as a proxy for innovation, is associated with social media use.

Social capital influences: Social capital is the scope of ties and linkages in a population through physical and communication means and well as by organizations that foster human collaboration or by bonding between people who possess resources (Putnam, 2001; Rupasingha, Goetz, and Freshwater, 2006). It was a key factor in a study of the digital divide for a survey sample of individuals in the US (Chen, 2003), as well as in a two-stage nationwide study of the decisions by persons to go online, subject to peer influences (Agarwal, Animesh, and Prasad, 2009). Thus, we propose that social capital is related to usage of social media.

The dependent variables are three social media usage attributes of number of Facebook, Twitter, and LinkedIn website visits over a 30-day period. Facebook and Twitter subscription have been included in previous digital divide studies (Pick, Sarkar, and Nishida, 2014; Pick Sarkar, and Johnson, 2015).

STUDY DESIGN, METHODOLOGY, AND DATA

Data

Data on various dependent and independent variables for this study were collected from multiple sources. Data on independent variables such as population, ethnicity, employment, income, governmental support for education, and sales revenue generated by publishers were obtained from various Census sources such as the US Decennial Census 2010, surveys conducted by the US Census Bureau such as the American Community Survey (ACS) of 2012, Local Education Agency (School District) Finance Survey of the National Center for Education Statistics of 2009, and US Economic Census of 2007. Data on US county-level social capital come from Pennsylvania State University's Northeast Regional Center for Rural Development (Rupasingha and Goetz, 2008). While data for several independent variables are obtained for the period 2010-12, social capital data are from the year 2009 which is the latest year for which such data are available. For dependent variables, data on the three social media dependent variables, usage of Facebook, Twitter, and LinkedIn, were extracted from Esri's Business Analyst software (Esri, 2014). Esri computes estimates of these dependent variables by combining 2013 geodemographic segmentation data with Doublebase® 2012 data from GfK MRI. Doublebase® 2012 data consist of an integration of information from four consumer surveys. The relevant data collection and estimation methodology statement for dependent variable data extracted from Esri's Business Analyst can be found at Esri (2015).
Usage of such data for US digital divide studies is unprecedented in the literature. Since all dependent variables, except for three, were from the three-year period 2010-12, time simultaneity has been assured for them. The fact that data for three of the independent variables lags by 3-5 years is justified as follows. Professional, scientific, and technical services employees are from the Economic Census of 2007, which was the latest date at which the variables were available. The 2009 variables of local government educational expenditures and social capital derive from specialized sources that do not have recent release dates. We feel the one-year lag for the period 2010-2012 is acceptable for these two variables, since they are not known to change rapidly year-to-year. All variables were converted to per capita whenever possible; variable definitions, sources, and descriptive statistics (N = 3,109 counties) of the dependent and independent variables are in Table 1.

Methodology

The methodology comprised techniques of descriptive statistics, correlation analysis, mapping of variables using a geographic information systems (GIS), testing spatial autocorrelation for the social media dependent variables, and ordinary least squares regression (OLS). For descriptive statistics, mean and standard deviations were computed for dependent and independent variables, in order to gauge the averages and extent of variation for all U.S. counties (Field, 2009). Correlation analysis was applied in order to screen the independent variables for multi-collinearity (Field, 2009, Hair et al., 2010).

Geographic Information Systems (GIS) can be utilized as an exploratory method to spatially describe and understand patterns of distribution of variables (Longley et al., 2011). In this investigation, GIS mapping is done to observe outlying values for the variables, with focus on the social media dependent variables. Given our sample of 3,109 counties, map displays reveal key trends, without overloading the display.

A key question is this study is whether social media usage in US counties shows statistically significant patterns of agglomeration of high and low values, or is social media usage in US counties spatially randomly distributed. We diagnose spatial autocorrelation – a common problem plaguing many technology diffusion datasets using Moran's I test statistic. The Moran's I test is inferential; the null hypothesis is that the values of a variable are randomly distributed spatially. Its interpretation is done by the p value for statistical significance (if p is not significant,

the variable is randomly distributed spatially). Further, if the Z score is positive, the values of a variable are more geographically agglomerated (high values located near high ones and low values near low ones). If it is negative, the spatial pattern resembles a “checkerboard” pattern, in which high values are surrounded by low ones and vice versa (Moran, 1950; Openshaw, 1984).

Following the mapping analysis, ordinary least squares (OLS) regressions were performed for each social media usage dependent variable, in stepwise order, allowing in only those of the independent variables with significance levels of equal or less than 0.05. As an additional test of multi-collinearity, the variance inflation factor (VIF) was computed for each independent variable. We utilized the common cut-off of 5 or greater for VIF to be of concern (Myers, 1990) and no multicollinearity problems were detected. Three diagnostic tests were administered to ensure that regression assumptions were met. Joint Wald Statistic is a test of the joint significance of several coefficients of individual independent variables (Wald, 1943). The Koenker (BP) Statistic Test is a test for heteroscedasticity, i.e. the variance of the residuals is not constant (Lyon and Tsai, 1996). The Jarque-Bera Statistic is a goodness-of-fit test of whether sample data, in this case regression residuals, have skewness and kurtosis that correspond to a normal distribution (Jarque and Bera, 1980). Additionally, regression residuals were tested for the presence of spatial bias using Moran’s I test statistic. Model relationships which result in spatially random errors are regarded as valid. If errors in the model fit are spatially autocorrelated, it implies that the geographic forces are exogenous to the conceptual model. In case Moran’s I testing indicates that regression residuals are not spatially randomly distributed, regressions results have to be treated with caution.

REGRESSION FINDINGS

The regression findings for the entire country indicate that the most important determinants for the three social media variables are college graduation, young dependency ratio, proportion working age population, and percent urban. As seen in Table 2, the most important determinant is college education. This is in concert with other studies of U.S. counties (Author, 2005), household surveys of the U.S. (Chen, 2013), sample of U.S. states (Author, 2015), and international samples of nations (Baliamoune-Lutz, 2003; Yates et al., 2011). The mechanism may be that college educated people tend to be more conversant with social media through greater exposure to ICTs and the web during their years of education. That LinkedIn has the strongest education effect may be due to the enhanced presence of college educated users of LinkedIn compared to Facebook and Twitter.

Demographic influences on ICT and social media have been reported in studies of Japan (Author, 2014) and the U.S. (Author, 2015). In the present study, both young dependency ratio and urban are positive; while for Japan, farm population is associated with reduced ICT usage including Facebook and Twitter, which implies that percent urban would increase them. On the other hand, young dependency ratio reduced some ICT variables and Twitter. This somewhat surprising finding is ascribed to young families being located in Japan mostly in rural areas, which would tend to have lower ICT and social media use.

Working age population has a strong positive correlation for all three social media indicators. This finding differs from the unimportance of proportion employed civilian workforce in a regression study of the U.S. states (Author, 2015). Service occupation is significantly associated with Facebook and Twitter use, although less strongly that for overall workforce. The findings on service occupations correspond to the importance of professional and service

occupations for payroll and receipts in most technology sectors for U.S. counties in 1997-2000 (Author, 2005) and to the significant relationship of employment in services to technology level for 164 European Union sub-national regions in 27 European nations (Vicente and Lopez, 2011).

For the U.S. county sample, urban location is related to usage for all three social media variables, although its strength of association is highest for Facebook, followed by Twitter and LinkedIn. This may be the result of Facebook, versus Twitter and LinkedIn, having more areas of low use in rural regions including Appalachia, the lower South, and the southeast border area of Texas. The finding contrasts with lack of urban correlation for Facebook and Twitter for the U.S. states in 2010 (Author, 2015). However, it is similar to the finding for Japanese prefectures of an inverse relationship of proportion farm population with Facebook and Twitter users per capita in 2009-2010 (Author, 2015). The lack of effect for U.S. states might be due to the larger unit of analysis, i.e. state versus county, not being fine-grained enough to register the

differences in and around the numerous American metropolitan areas. However, the finding corresponds to a survey study for the U.S. in 2010, in which 78 percent of urban adults used the Internet, versus 70 percent for rural dwellers (Perrin and Duggan, 2015, page 9).

The findings for influences of ethnicities varied among the three social media variables. For Facebook there is inverse association with Blacks and Hispanics, while for Twitter there is association with Asian and Blacks, and for LinkedIn association is present with Asian. We reason that Asian has generally opposite effect from Blacks and Hispanics, with Twitter being an exception for Blacks. This is based on other studies with similar findings (Perrin and Duggan, 2015; Author, 2015). For American adults in 2010, percent that used the Internet varied from 90 percent for Asians to 71 percent for Hispanics and 68 percent for Blacks (Perrin and Duggan, 2015, page 7). For U.S. states in 2009-2010, findings for contemporary technologies indicate positive association of Asians to a variety of ICT variables, while Hispanics associations are inverse. This included a positive Asian association and inverse Hispanic association with Facebook users, although no effects were evident for Twitter users (Author, 2015).

The results for the metropolitan, micropolitan, and rural subsamples largely correspond to those for the nation as a whole (Tables 2 and 3). Accordingly, only major differences from country-wide findings are noted here for the subsamples.

Metropolitan subsample: The main difference from the national results is an inverse relationship of construction occupations with Twitter Use. This finding was not noted at the state level in 2009-2010 for Twitter or Facebook (Author, 2015). A possible indirect explanation is that areas having a high proportion of construction workers tend to be less educated and of lower income, which are known to decrease social media use. The direct effect related to the impacts of construction occupations is unexplained.

Micropolitan subsample: For the micropolitan subsample, there is a stronger association for the service occupations on all three social media variables than for the country or metropolitan samples, although correspondence to rural sample results. It may be that in the smaller cities and towns of micropolitan or rural America, there are proportionately more service workers, so with more presence, their influence on social media is greater. Another explanation is that social media may be a more important form of services communication between service workers and spread-out or even isolated service customers.

Social capital unexpectedly reduces Twitter and LinkedIn use. This is contrary to prior reported positive effects, at the U.S. state level, of social capital on desktop, internet, and positive effect broadband use and of the social-capital proxy variable of immigrant population on Facebook and Twitter (Author, 2015). We reason the influences for LinkedIn and Twitter are attributed to a substitution effect, in which those counties having strong social capital have lower average need for citizens to access LinkedIn, since those with a strong physical social network, usually mostly local or regional in extent, have less need for the worldwide professional networking of LinkedIn or social networking of Twitter. Facebook may be more valuable to users than Twitter or LinkedIn on a local basis, since it can contribute more to supplementing (rather than substituting for) existing physical networking. The positive effect of professional/scientific/technical workforce, limited to only LinkedIn, is due to LinkedIn's market emphasis on business and professional people. The inverse effect on Facebook of local government education expenditures is unexplained.

Rural subsample: This subsample's inverse association of social capital with LinkedIn corresponds to the explanation just given for micropolitan. Likewise, there is the positive effect

of professional/scientific/technical workforce on social media corresponds to the nation. The inverse effect on LinkedIn of local government education expenditures is unexplained.

Before concluding this section, it is important to observe that all coefficients in the regressions (results in Tables 2 and 3) are statistically significant at the .001 level. This is due to the large overall sample (n = 3,109 counties) as well as sub-sample sizes of metropolitan (n = 1,161), micropolitan (n = 637) and rural (n = 1,311) counties. It is therefore essential to examine the magnitude of the standardized coefficients to determine which independent correlates have higher associations with social media usage. Further, given the large sample size fallacy, it is important to focus on effect size (Lantz, 2013; Sullivan and Feinn, 2012). According to Sullivan and Feinn (2012), the adjusted r-squared is an acceptable effect size index for studies that examine associations between variables. Adjusted r-squared values range between approximately 0.50 and 0.90 in this study with a couple of exceptions: for Twitter and LinkedIn in the rural subsample. Such effect size is characterized as large (Sullivan and Feinn, 2012) indicating that large sample size fallacy (Lantz, 2013) has been addressed.

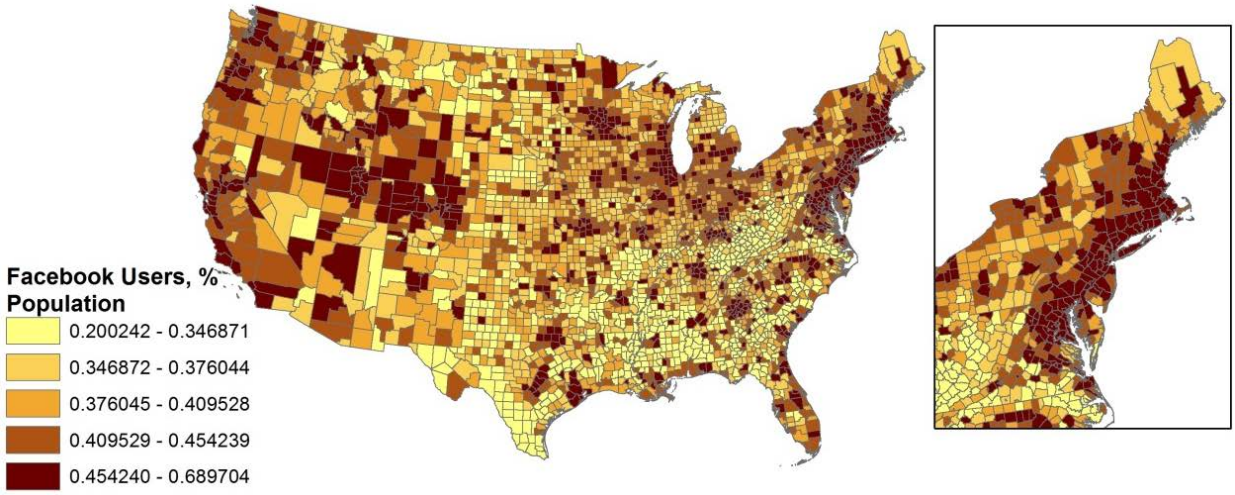
SPATIAL PATTERNS OF SOCIAL MEDIA USE

In this section, the descriptive maps for the three social media variables are examined and interpreted, as well as the spatial autocorrelation findings. Since the maps show 3,109 counties, it is beyond the scope of this paper to examine their many hundreds of descriptive features, relationships, and differences, and accordingly this paper points only to the most prominent features nationally.

For Facebook (Figure 2), the findings show considerable range of percentage Facebook use, ranging from low use (20-35 percent) to high use (45 to 69 percent). Low levels are most evident in the southwest Texas border area, rural parts of the Great Plains stretching north-south from the Dakotas to Texas, the mid to lower-central South and in Appalachia and rural, inland parts of the Carolinas and Georgia. High areas of use are seen in the Boston to Washington megalopolis (see cutout on Figure 2), Atlanta, Chicago-Milwaukee, Minneapolis, Denver and Salt Lake City metropolitan areas, Seattle and Portland metro areas, San Francisco-San Jose, and parts of Southern California (i.e. San Luis Obispo, Santa Barbara, Orange, and San Diego Counties), but excluding Los Angeles County. This finer geographic detail was missing in a prior study's state map of Facebook users (Author, Figure 2), which for instance did not show the prominent features evident at the county level for Boston-Washington megalopolis, southwest Texas or Appalachia. Overall, these findings reflect the positive influence of location in large and creative metropolitan areas and reducing effect of poor and remote rural counties. The high Facebook levels in Denver, southern Wyoming, Salt Lake City, and surrounding Rocky Mountain areas have not been previously reported.

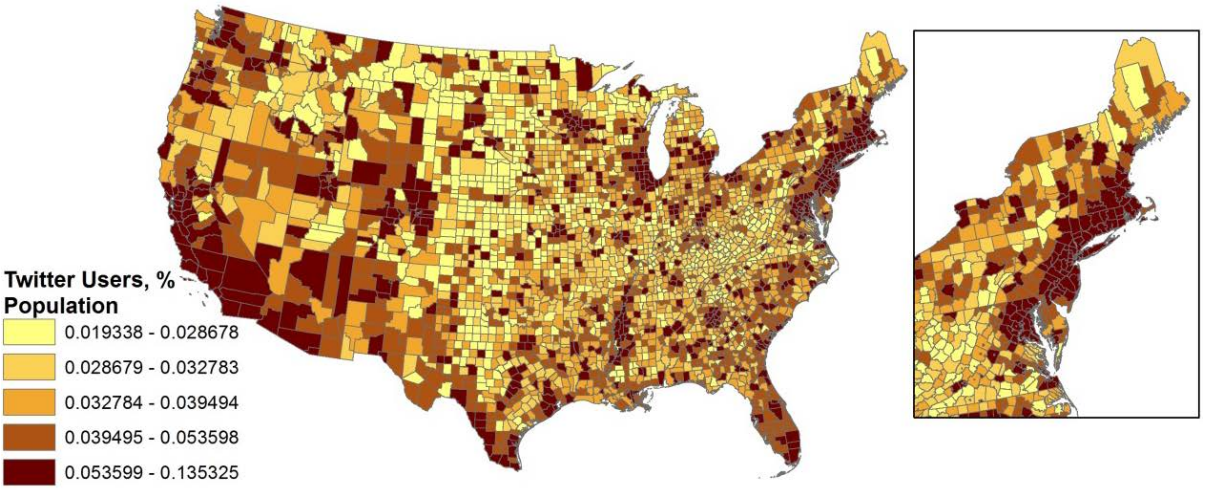
The concept of megalopolis originated through Jean Gottman's study of the massive combined metropolitan areas of the Northeast coastal region stretching from Boston to Washington (Gottman, 1961). In 2000, the Northeast megalopolis was estimated to have 49.6 million population or a sixth of the U.S. population (Short, 2007). The high Facebook adoption by a half to two thirds of the population in this vast, dense megalopolitan region magnifies the social media impact, since the tens of millions of users are physically within several hours drive time of each other. This region also reflects the key positive determinants of Facebook use that were already discussed including college education, urban, working age population, and presence of significant Asian population in its large cities.

Figure 2. Spatial Distribution of Facebook Users (% Pop), U.S. Counties, 2012



The spatial distribution of Twitter users (Figure 3) corresponds generally to the pattern to Facebook, with however the following differences: (1) the levels of Twitter use on the southwest border of Texas are much reduced compared to Facebook use, (2) usage in Southern California is substantially higher and includes all the counties in metropolitan Los Angeles and San Diego, (3) Denver and surrounding Rocky Mountain region is high in usage, but not as extremely high as Facebook, and (4) Appalachia and the mid-central South are moderate rather than very low for Facebook.

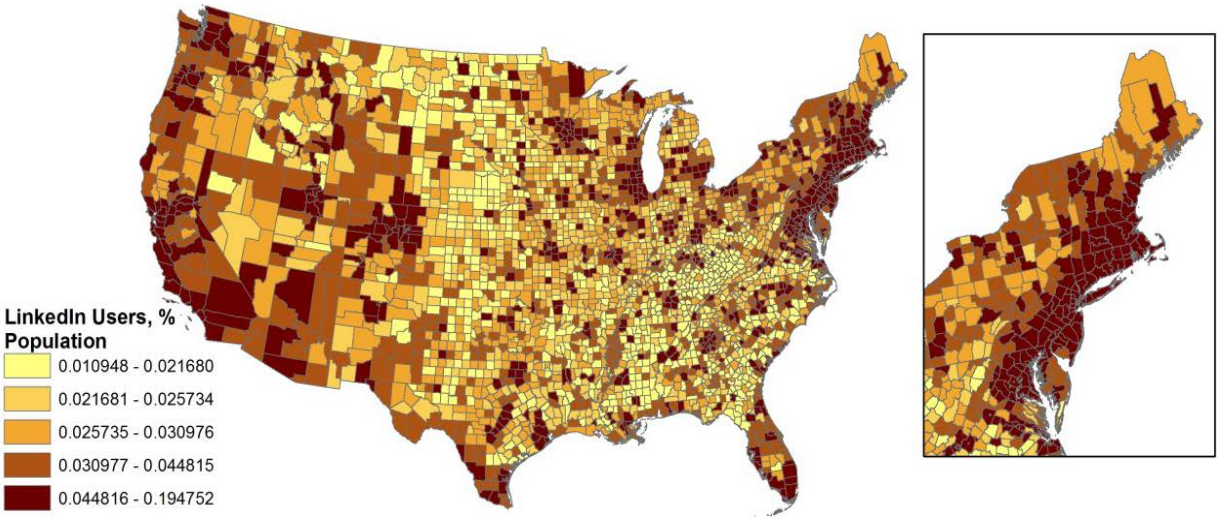
Figure 3. Spatial Distribution of Twitter Users (% Pop), U.S. Counties, 2012



The high Twitter use in the entertainment industry cluster of southern California might stem from Twitter's greater entertainment aspect than for Facebook or LinkedIn, while Twitter's relatively higher use in the lower-central South and Appalachia might be due to Twitter's simplicity and low storage needs, which are more suitable to the less affluent and educated population in those areas. LinkedIn's spatial distribution (Figure 4) resembles Twitter's, but has a north-south band of low use that extends from North Dakota to the Texas Panhandle and is unexplained.

Spatial autocorrelation analysis of the dependent variables (see Tables 2 and 3) reveals that results for Moran's I are highly significant for the country, metropolitan samples, inconsistent for the rural samples and not significant for the micropolitan sample. This reflects that the social media use is highly agglomerated in its metropolitan portion, which also influences the agglomeration level of the country as a whole, while micropolitan counties are less influential on their neighbors, resulting in lack of agglomeration of counties. For rural areas, agglomeration is significant for Facebook, for unknown reasons, while Twitter has significant inverse Moran's I value, implying that there is a trend towards lack of spatial autocorrelation, while there is a random spatial distribution for LinkedIn.

Figure 4. Spatial Distribution of LinkedIn Users (% Pop), U.S. Counties, 2012



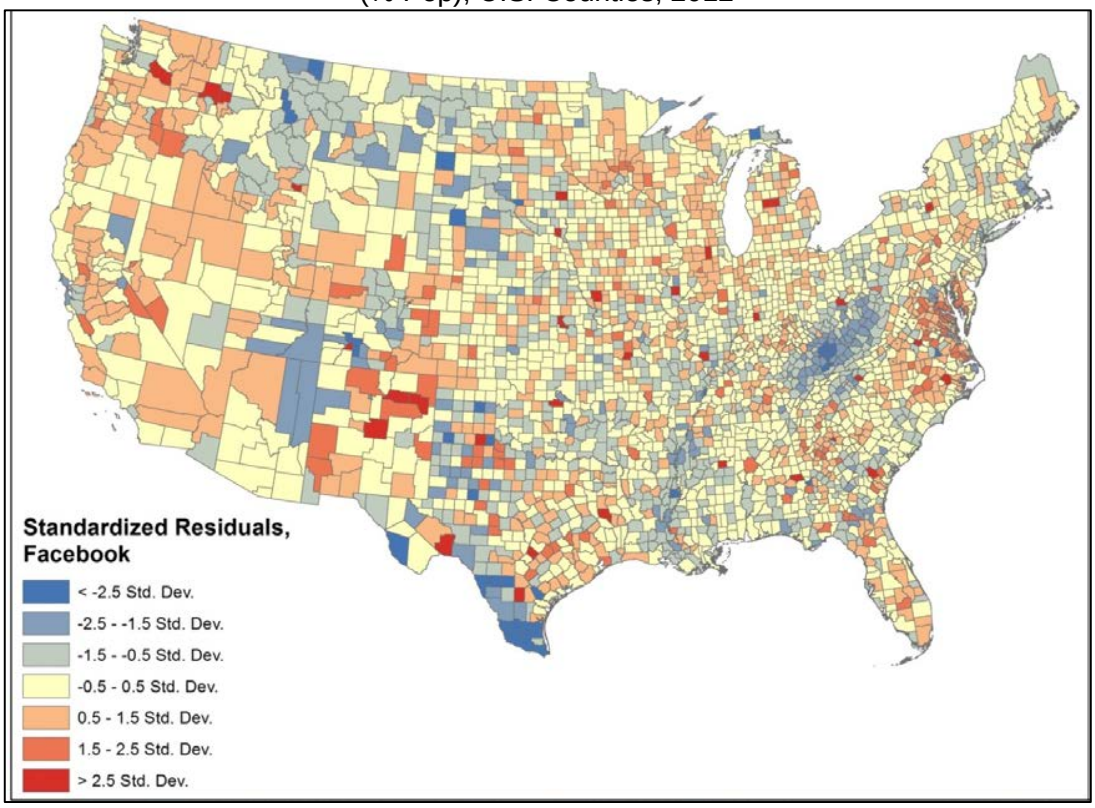
Spatial analysis went further and computed the extent of randomness of spatial autocorrelation, as measured by Moran's I, for the residuals of the OLS regressions. The results indicate a low spatial autocorrelation, compared to the high spatial autocorrelations values of the original variable, for the country and metropolitan samples, while the residual spatial autocorrelation level for the Micropolitan and Rural samples is random, except for an inverse Moran's I value for Twitter. Hence, in general, the OLS regressions have either reduced substantially or eliminated the spatial autocorrelation present in the original dependent variable, which means that the model and its independent variables are able to account quite fully for the very high autocorrelation for the observed dependent variables. Nevertheless some agglomeration remains, in particular for Facebook for the country sample and for all three social media variables in the metropolitan subsample, so those findings must be viewed cautiously. Figure 5 is a map of the standardized residuals for Facebook at the country level, and it is evident that the Facebook spatial autocorrelation persists in the residuals and is similar in pattern to the spatial autocorrelation pattern the Facebook raw variable (i.e. compare Figure 5 to Figure 2).

DISCUSSION OF RESULTS

This study has confirmed some well-known determinants from the digital divide literature. In particular among model variables, very prominent ones confirmed to have influence on social media, are age structure (Author, 2015), college graduation (Baliamoune-Lutz, 2003; Author, 2005; Author, 2008; Vicente and Lopez, 2011; Yates, Gulati, and Weiss, 2011; Chen, 2013), urban location (Arai and Naganuma, 2010; Fong, 2009, Chen, 2013), and ethnicity (Author,

2005; Perrin and Duggan, 2015; Florida, 2012). Among these are a pair of variables, urban location, and college graduation, which have commonly been closely correlated (Chen, 2013). Although missing from this research due to multi-collinearity, per capita income is often also correlated with this pair, so that it should be considered for inclusion in future research, perhaps to replace one or two in the triad.

Figure 5. Distribution of OLS Regression Residuals (Standard Deviations) for Facebook Users (% Pop), U.S. Counties, 2012



Although professional, scientific, technical service occupation had a strong influence on ICT in a prior U.S. county study (Author, 2005), it was unimportant in the findings, except for LinkedIn for the micropolitan and rural subsamples. The difference is ascribed to a shift in the dependent variables, which, for the earlier study, were revenues and business receipts and payroll for the IS-Data Processing industry, broadcasting-telecommunication industry, and motion picture-sound industry. While for those complex sectors, the scientific/professional workforce would clearly have an impact, that impact is much less likely for the present countywide consumers of social media, who tend to be younger, educated individuals, but not necessarily technically inclined. Accordingly, for social media use, county policymakers need not concentrate on workforce development, by they but it should do to boost productivity in complex, digital industries.

Social capital is an unexpectedly weak determinant country-wide. For the subsamples, its effect was slight and only present as an inverse determinants in the micropolitan and rural samples for Twitter and LinkedIn. We ascribe the inverse findings to the substitution effect for physical social capital that was discussed earlier. Construction workforce had a slight and mostly opposite,

inverse effect. This is unexplained and points to further research to try to determine the mechanism. The Spatially Aware Technology Utilization Model (SATUM) is applicable to this investigation. Nearly all the independent variables have at least some empirical association with the social media. The only exception is personal income, which was eliminated in the present study due to multi-collinearity. The present SATUM model has the potential to be applied to small geographic samples of counties, with sample sizes as small as 50. For example, two areas identified descriptively to have high usage of social media, western coastal counties stretching from Washington State to southern California and the Northeast megalopolis, might be studied as subsamples to determine their determinants for social media. Likewise, the social media determinants in the Great Plains and middle South counties could be analyzed by regression to determine their determinants for low social media usage.

For large samples, with varied environments, geographically weighted regression constitutes an alternative way to aggregate results over distinctive geographies. However, for the full set of U.S. counties, it is problematical due to the irregularity of the county polygons across the nation, although it could be applied in sub-national regions such as Midwest with more consistently shaped boundary shapes.

Spatial autocorrelation in the present investigation is very useful in assessing extent of agglomeration for raw variables and for regression residuals. For such a large sample, it has the advantage to summarize systematically the extent of agglomeration, which the eyeball would miss.

Given the very large sample sizes, more complex models could be constructed with Structural Equation Modeling (SEM), path analysis, or econometrics. For SEM, the set of independent variables could be enlarged by selecting additional ones from the U.S. Population and Economic Censuses, American Community Survey using 5-year range of data, or other robust county samples. Although a theoretical model has already been tested by SEM for a worldwide sample of nations (Author, 2011), a more complex factor model could be formulated for U.S. counties, and relevant theory could be applied from that study. However, it is likely other relationships would need to be induced. A challenge would be to take geography into account, in applying SEM.

POLICY IMPLICATIONS AND LIMITATIONS

County governments can set ICT policies, as can metropolitan governments which are defined as area based on one or more county (U.S. Census, 2015). These governments can influence ICT policy, by providing their own public Internet services, fostering or supporting ICT training for citizenry, encouraging the hiring of local ICT graduates (Kvasny and Keil, 2006), encouraging and helping with incentives for service industries make greater use of IT including by small businesses. Regarding IT training, the governments need citizens to go beyond just completing courses or certificates, but to leverage the training for the “next step,” which might be further education or a closely-related job (Kvasny and Keil, 2006).
It is more difficult to develop polices based in demographic determinants of social media, since the population processes are not under the control of the county government. Nonetheless, the counties could focus their training options on demographic categories associated with more ICT usage, such as young, urban, affluent people. However, at the same time, social equity would push county policymakers in the opposite direction, to favor training for technologically underprivileged age groups in rural areas.

Although our study suggests that county policies not emphasize formation of social capital, an earlier study at the state level indicated strong impact from social capital, and it pointed to the need for state policymakers to emphasize it (Pick, Sarkar, and Johnson, 2015).

Limitations

One limitation is that the dependent variables were collected in large-scale industry surveys, which are subject to a survey sampling error. However, when a newer survey becomes available, longitudinal comparisons can be made for error checking. This also points to the limitation that the study is cross-sectional, so cannot recognize the magnitude changes of variables and varying influences over time. However, this limitation can be overcome by a future study that includes the present data for 2010-2012, along with data for a later period.

A limitation already mentioned is that the regression analysis does not model complex and/or bi-directional relationships. This can be addressed by using SEM, path analysis, or other techniques for analyzing complex models. A challenge for such studies will be to formulate a more complex theoretical model than SATUM, which could be derived from limited prior complex models, induction, and reasoning. Another methodology that could be applied to parts of the nation with fairly consistently shaped and sized polygons is geographically-weighted regression (GWR). This is a not a present limitation because the entire nation has polygons which are frequently irregularly sized and shaped, so GWR could not be applied. The study is limited by use of data that are from 2010-2012. More recent data on the dependent variables is available; however, many of the dependent variables are not updated, so it might be several years before a data set with good time simultaneity will be available. Finally a limitation is that case studies of counties are not available that could illustrate the SATUM theory and support or contradict the present empirical findings. If this need is met by developing case studies, interview questions would need to be designed to add higher levels of understanding of geographical aspects of county technology use.

CONCLUSIONS

This research has developed a conceptual model in which socio-economic variables influence social media use, with accompanying spatial analysis. The model is tested empirically by OLS regression, revealing that the key correlates of social media use are age structure, college education, young dependency ratio, working age population, and percent urban. The sample of U.S. counties is divided into subsamples of metropolitan, micropolitan, and rural counties, and analysis of those OLS findings allow comparisons to be made with the country-wide sample. The spatial analysis consists of descriptive mapping and spatial autocorrelation analysis both of the dependent variables and of regression residuals. This latter analysis reveals the U.S. to be highly agglomerated in social media for counties. At the extreme of high valued agglomerated counties is the Northeast megalopolis and coastal southern California stretching up to San Francisco and eventually to Seattle. There also is an area of high social media use that centers on the Rocky Mountain region from Denver to Salt Lake City. Area of low social media use include the Great Plains, Appalachia, and the mid lower South. Policy implications of the research are applied to formulation of county policies. Examples would be to encourage education, innovation, and training for service workers including for small businesses. This research points to further projects that could illuminate the county social media patterns, the forces that are related to social media use, and the geographic texture of usage in America.

Agile Software Development and Organizational Citizenship: A Behavioral Lens on the "Good Coder"

James Dipko
Cleveland State University
Email: j.dipko@csuhio.edu

ABSTRACT

Agile methods have emerged to promote software developer productivity, yet IS projects continue to face challenges. Meanwhile, IS research has provided limited evidence of the correlation between specific Agile development practices and higher levels of developer performance. This model development proposal will address these gaps in two ways: First, it will propose that specific Agile practices contribute to higher levels of job engagement. Secondly, it will propose favorable levels of job engagement influence stronger levels of both in-role and organizational citizenship behaviors.

KEYWORDS: Software Development, Agile, Organizational Citizenship Behavior, Job Engagement, Mediation

INTRODUCTION

Software projects are complex and costly (Guinan et al 1998; Li et al. 2010; Ply et al. 2012; Wiener et al. 2016; Hsu et al. 2016; Purvis et al. 2016; Ozer and Vogel 2015; Cecez-Kecmanovic et al. 2014; Conboy 2009; Harris et al. 2009; Xu and Ramesh 2008; Xu and Ramesh 2007; Chilton et al. 2005; Boh et al. 2007). The use of distributed software development teams has led to coordination challenges, team conflicts, and mixed approaches in performance management (Ramesh et al. 2012). IS development activities are strategic in nature (Ang and Slaughter 2001) and elicit high levels of business risk (Nidumolu 1996; Lee and Xia 2010). Administrative activities such as estimating, requirements elicitation, project planning, and system testing still depend on the input, output, and throughput of software developers.

A project's delivery time, cost, and quality pivot significantly on developer productivity. This is because the specialized knowledge of individual developers influences a project's execution success (He et al. 2007). According to Boh et al. (2007), the largest component of a firm's software costs is development labor. These costs are high because development work is complex, lacks repetitiveness, and is difficult to automate. Developers are consistently challenged to meet deadlines and maintain high standards of quality and productivity. This pressure may become a source of stress for individual contributors (Srivastava et al. 2015), especially those who are not fully engaged in the work that they do. In turn, the perceived strain of the work environment can attenuate performance, or lead to burnout (Nahrgang et al. 2011). Fluid requirements and shifting technologies invoke unplanned reprioritizations, re-tooling, and development re-assignments.

Methodologies such as Agile, Scrum, and eXtreme Programming structure project work in ways so that developers can flourish in an uncertain environment. Rather than executing project phases linearly, these lean and minimalist methodologies are said to place developers in a better position to succeed through (1) smaller iterative work cycles and (2) strong emphasis on

knowledge sharing, team collaboration, and (3) frequent interactions. These processes are believed to benefit not only immediate delivery cycles, but also job satisfaction (Tripp et al. 2016) and the broader organization (Ply et al. 2012).

Software developers spend considerable time and effort dealing with abstract information (Perlow and Weeks 2002). Their skillsets must adapt to emerging technologies, development platforms, and languages. Developers must also be versatile and willing to share knowledge with one another (Hoda et al. 2012; Ozer and Vogel 2015; Strode 2016; Chapman et al 2017; Kudaravalli et al. 2017). Cross-functional (varying domain expertise) teams of developers become more essential in complex project environments (Fong Boh et al. 2007; Harter and Slaughter 2003; Deephouse et al. 1995). Agile-centric activities such as collaborative development, daily standup meetings, and iterative planning are believed to encourage these collaborative behaviors. Work plans are structured incrementally, and executed in short cycles (1-2 week iterations). Expectations for high performance, productivity, and throughput from individual contributors are expected in these contexts. Furthermore, software developers will be expected to perform outside of their traditional job duties as methodologies evolve and change (Chih-Ching et al. 2013, Shin et al. 2014). High expectations and demanding workloads can be optimally managed when people (a) feel engaged in the work that they are doing, and (b) that the work that they're doing is important (Maslach et al. 2001). With the optimal conditions and resources, employees can remain engaged, even when under high demands or workloads (Bakker and Shaufeli 2008).

Developers command significant investment; academic training, organizational training, wages, benefits, administrative costs, hardware, and tools are needed to realize material outcomes from development staff (Rasch and Tosi 1992; Surakka 2007). To perform their job function in organizations, developers must be knowledgeable about technologies, the business domain, user needs, and the tools required to build applications (Mehta and Bharadwaj 2015; Vidgen and Xiaofeng 2009). Due to this multifarious expertise, the residual benefits from each developer's knowledge can be a powerful source of operational advantage. The challenge for IS organizations is to provide an environment where this knowledge can be harnessed to benefit (a) immediate work contexts and (b) the broader organization without (c) attenuating expected job performance. For that to happen, developers must feel engaged enough with their jobs so they are proactive and affiliative in dynamic environments – in other words, to reflect what is commonly known in organizational research as the behavior of "good soldiers" (Organ 1988). According to Sonnentag (2003), "Proactive behavior is crucial in modern organizations characterized by fast changes and reduced supervision. To show flexibility, to meet customer demands, and to compete in the global economy, organizations need employees who go beyond narrow task requirements (p. 519)." If a developer's engagement is limited only towards the immediate needs his/her assignments, a developer is less likely to make contributions to the work his/her colleagues are doing, and the organization at large. Conversely, if developers are going above and beyond, projects and the broader organization only stand to benefit.

Organizational citizenship is a theoretical basis to further investigate factors influencing these "good soldier" (or in this case, "good coder") behaviors. Even though Organizational Citizenship Behavior (OCB) research is well-established, prolific, and has addressed a variety of job contexts, there is little empirical evidence concerning antecedents and consequences of these behaviors specifically among IS development personnel (Chou et al. 2013; Yoon 2008). Furthermore, research concerning development methodologies and their associated outcomes have been largely non-empirical and anecdotal (Mangalaraj et al. 2014; Li et al. 2010; Ply et al. 2012; Faraj and Sproull 2000). To address these gaps, this model development paper will address the following two research questions: (1) Are software development practices

positioning developers to feel more engaged in their work? (2) If so, does this engagement promote better in-role performance and higher levels of organizational citizenship?

LITERATURE REVIEW

Software development involves the utilization of knowledge to design software features and correct flaws or errors (Ozer and Vogel, 2015). In this study, the translation of user or system specifications into software represents the characterization of developer's main job role. Software development is intellectually challenging and socially ingrained. Developers must code productively and collaborate effectively with others (Kudaravalli et al. 2017). According to Maruping et al. (2009), software development is challenging because it is a complex activity requiring overlapping skills, high levels of coordination, and effective project management. A diverse knowledge base allows developers to react quickly in dynamic environments, provide good solutions, and estimate the impact of change effectively (Li et al 2010). Developers may encounter variegated, ambiguous, and complex information as work shifts and change. Many times, requirements are uncertain (Sheffield and Lemeteyer 2013), and developers must adjust accordingly by refactoring or changing code.

The need to respond rapidly to changing user requirements is essential to project success. According to Perlow and Weeks (2002), software developers (knowledge workers) could experience mismatches between skills and abilities and job requirements. With rapid shifts and changes to technologies, software developers must often undergo paradigm shifts in development approaches (Armstrong and Hardgrave 2007). In recent years, techniques such as Agile software development have been introduced to help software developers work more efficiently in these rapidly changing environments. Theory-motivated, empirical, and behavioral research on software development is somewhat sparse – furthermore, it almost always emphasizes teams. The findings, however, can be used to uncover what is generally expected of individual developers on a day to day basis. For those developers demonstrating "good soldier" behavior, organizations can learn how to better maximize the return on costly development staff investments. Orienting these individual contributions towards colleague success and broader organizational success can result in positive inertia and residual feedback loops into subsequent projects.

As a point of departure, identifying what software developers do in their job is critical to categorizing and distinguishing these behaviors. Thus, the objective of the following section is to gain a better understanding of what developers "do", and link those behaviors to software methodologies designed to encourage them.

Software Development Methodologies

Agile-based methodologies have emerged to encourage (1) incremental management of workloads, (2) more effective response to changes (Highsmith and Cockburn 2001), (3) the use of self-managing teams (4) joint ownership of code and (5) delegation of responsibilities to various team members (Maruping et al. 2009). The Agile Manifesto (Beck et al. 2001), an industry-recognized document outlining Agile's basic tenets, focuses on project activities which emphasize individuals, interactions, and being responsive to change. An Agile developer must be accepting of rapid shift and change with the work that is being done. On any given day, developer assignments may shift due to changes in priority or user requirements. These rapid shifts can influence a developer's perception of his / her job in very volatile ways. At times, the need for flexibility and adaptiveness may require role shifts – developers may need to become testers or even requirements analysts. The work being done is meant to feed back into the next

set of team activities, including future iterations, retrospectives, and standups. More specifically, Agile is oriented towards ensuring each developer is reflecting on past work where needed, and focusing on the immediate needs of each delivery cycle. Tripp et al. (2016, p. 273) provide a summary of several Agile project management activities to facilitate these behaviors, which are summarized as follows:

(1) **Stand up meetings** - frequent (usually daily) where each developer shares prior progress, planned progress for the day and obstacles.

(2) **Iterative delivery** - the process of planning and delivering software in iterative, small chunks, rather than in their entire over a single, prolonged cycle.

(3) **Retrospectives** - meetings held at the end of each iteration to identify successes and improvement opportunities from the previous cycle.

(4) **Burndown** - visual representation of the work that has been completed and the work remaining in the current release.

These Agile management activities are intended to "vertically load" the responsibilities of each developer, combining design, development, testing, and other tasks into a single developer's responsibilities. In addition to these project management activities, there are specific technical approaches employed by teams, including continuous integration, test-driven development, and paired programming.

Dawande et al. (2008) provides an overview of eXtreme Programming (XP), which is considered a foundational "Agile" methodology. Prior to Agile methods, traditional waterfall projects would incur significant disruption when unforeseen changes were need during project execution. XP encourages the practice of paired programming, where two developers work concurrently on software at the same time. Developers participating in paired programming must be willing to share knowledge and co-locate with their partner at the same workstation. In pairing, effort is required by developers in multiple dimensions including (1) the coding/testing effort itself (2) forming the pair and (3) sharing knowledge. Advanced developers, if paired with novices, may require even more effort in terms of knowledge sharing, mentoring, or helping. Developers who have never worked with one another will also require more effort to get the pair formed and build rapport. Depending on a project's objectives, pairing (which is thought to reduce effort) may or may not be preferable over solo programming (which is thought to reduce development time). According to Dawande (2008)," pair programming may be better suited for novel projects where completion time is less of a concern, but there is a strong need for every team member to understand the nuances of the development (p. 90)." Therefore, methods such as paired programming, while designed to account for rapid/unforeseen shifts in requirements, still come at a cost.

According to Nelson and Armstrong (2009), methodological changes have led to a paradigm shifts in what is expected of developers. Over time, organization are becoming less reliant on lower level coding expertise, and more reliant on abstract skills normally demonstrated by "well-trained analysts (p.273)." In other words, developers are expected to think at higher, more abstract, and more complex levels than they have been in the past. Therefore, the nature of programming as a skill has undergone an evolution from simply coding designing, analyzing, and assessing reusability of modules. For those trained in a more traditional sense of programming, where lower-level coding skills are almost entirely emphasized, there has been a need to make significant transitions in work ability and style. One example of this shift is illustrated by the transition from structured programming to object oriented programming. In

their comparison of programming background and fitness with object-oriented paradigms, Nelson and Armstrong (2009) determined that paradigm shifts can take an extensive amount of time and can vary in difficulty depending on whether an individual developer's cognitive style fits with the paradigm in question. This may require organizations to invest more in training and expertise consultation when there are shifts. At the same time, for such training to be effective, individual programmers must also be open to change, interested in their work, and resistant to anchoring in prior methods or ways of thinking.

Lee and Xia (2010) investigated the antecedents and consequences of software development agility, which is the extent to which teams can effectively and efficiently respond to user requirements. More specifically, they studied the influence of how Agile team autonomy and diversity influence the ability for teams to respond to changing requirements efficiently and effectively. Agile developers may be expected to self-organize into different sub-teams when appropriate, participate in standups or retrospectives to keep work moving and to identify improvement opportunities, program in pairs, make decisions without formal or explicit authority to do so, continuously review changes with peers or users, and, most importantly, meet the objectives of each iterative cycle. In their model, Lee and Xia (2010) determined that teams with higher levels of autonomy are less likely to accommodate unplanned changes to a certain extent. This may result in less desired functionality, but can also mean the team can deliver a minimally viable product on time and within budget. Therefore, organizations should consider trade-offs when giving teams the authority to make their own decisions.

Kudaravalli et al. (2017) studied the impact of software development team configuration and team conflict on team coordination success. Their model emphasized the importance of team members collaborating with one another to build working software, especially in design phases. Design coordination, which must deal with ill-structured and abstract information, was optimized around decentralized team configurations. Coordination in technical tasks, however, evoked more coordination success when teams centralized themselves around a specific expert. Organizations which buy into complete centralization or decentralization of teams may find themselves at a cross roads when designs need to move into coding phases. Furthermore, highly interdependent teams that are decentralized need developers who can work effectively with others, remain productive even in times of team conflict or disagreement, and adjust their work style depending on the phase of a project.

Mangalaraj et al. (2014) studied in the influence of paired designing and design patterns on the quality of design outcomes. Using theoretical foundations based on distributed cognition and collaborative design, they determined that software designs articulated by high performing individuals were of similar quality to designs articulated by pairs. This illustrates collaborative work methods based on Agile team configurations may not derive reported benefits, especially when individual contributors vary in skill and ability. Furthermore, paired design teams were found to take more time than individuals. This also underscores the importance of individual level performance and its ultimate influence on overall outcomes. Even though software design and development is almost always done in team settings, organizations must not lose sight of the fact that individual level contributions matter and can greatly influence overall outcomes. Rather than emphasizing collaboration, Mangalaraj et al. (2014) determined that establishing good design patterns may have a better impact on delivery of high quality solutions.

Nidumolu and Sumbramani (2003) investigated the influence of standardized or decentralized control mechanisms within project teams. Developers are often faced with an uncertain environment or unforeseen changes in requirements. Organizations must decide whether to centralize or decentralize controls and outcome measures for project teams. Controls can be

oriented towards behaviors (methods) or results (outcomes). Their study determined that in uncertain environments, standardized outcome controls and decentralized behavior controls (granting decision authority to teams) can have favorable influences on performance. When organizations rely on vertical coordination to reach critical decisions, development teams may lose momentum or inertia while awaiting those decisions. And, because methods such as Agile are based on autonomous teams, organizations must be able to rely on development team members to work effectively with one another and avoid conflict when critical decision points are reached.

Maruping et al (2009) also investigated the impact of controls on software development performance. More specifically, they sought to understand how control mechanisms and requirements uncertainty interacted with the use of Agile practices. Control mechanisms are especially salient in Agile teams. According to Maruping et al. (2009), "agile methodologies suggest that team members be largely responsible for managing their own processes, making decisions about how project goals will be attained, and delegating task responsibilities to various team members (p. 381)." This further illustrates a serious challenge for organizations – on one hand, the efficiency of development teams relies on self-led, self-motivated individuals and teams. On the other hand, development labor represents the greatest degree of software costs. Maruping et al. (2009) determines that project leaders must be judicious in how they relinquish this autonomy to teams. They found that autonomy is optimized when it is given to entire teams, not just individuals. Furthermore, specific performance objectives must be given, otherwise gains from autonomy will not be optimized. Overall, Agile can favorably influence project outcomes the most when requirements are uncertain and teams are granted autonomy in conjunction with the right mix of outcome controls.

Vidgen and Wang (2009) conducted a case study to compare software development team agility between two teams: the first team utilized XP (eXtreme Programming), and the other team utilized a traditional waterfall approach. The XP team incrementally delivered software in one-week cycles. Each user story (requirement) began with a planning exercise, followed by coding, testing, and integration steps. For those on the XP team, developers were held to strict expectations in terms of delivery in these cycles. Developers were timed as they coded, studied, and took breaks. Even though the rate of change on the team was high, the study illustrated the rigorous, stringent, "assembly-line" nature of programming in an XP environment. The XP team also experienced occasional difficulty dealing with pace, as well as slow-downs when communication between developers and users became extraneous. Developers were expected to share feedback with one another and leverage the work being done so it fed back positively into the next iteration. Furthermore, the XP environment was structured in such a way so that each individual contributor needed to be responsible and willing to share knowledge with one another.

Xu and Ramesh (2007) investigated the degree to which software firms adhered or tailored their implementation of standardized processes. Organizational contingency theory states that firms may decide to "tailor" software development processes to unique technologies and business domains. Some of the factors a firm may take into consideration when determining whether to adopt a tailored approach depends on several factors, many of those impacting the developers. For example, a team of inexperienced developers may work more advantageously in an iterative environment which emphasizes peer reviews and feedback. Projects experiencing budgetary or time constraints may decide not to utilize daily/frequent standup or planning meetings, to free up a developer's time to conduct design and development activities. Projects dealing with a significant amount of ill-structured requirements or a complex business domain may decide to emphasize more documentation than what would normally be required in an

"Agile" environment. Therefore, a project's specific needs and context may expect different things from developers over the course of time.

Tiwana and McLean (2005) investigated the influence of expertise integration on overall team creativity. Creativity can be essential to successful outcomes because development involves the "generation and evaluation of new ideas, designs, solutions, and artifacts (p. 18)." Exploring multiple solutions can give teams a better chance of finding one that minimizes costs and supports the minimally viable products advocated by Agile approaches. Expertise from varying domains is required to arrive at a variety of solution options. This underscores the importance of individual contributors feeling connected enough with their teammates to explicate various knowledge backgrounds and to propose different ideas. In Tiwana and McLean's (2005) model, expertise integration results in a set of mutually understood and negotiated sets of beliefs. The team must have favorable levels of relational capital (ie trust, reciprocity) and absorptive capacity (recognizing potential of one another's expertise) to successfully integrate one another's expertise. Overall, these findings suggest that developers on teams with varying types of domain knowledge cannot work well with one another unless there is some degree of social connectivity; developers must be able to coordinate and work effectively with others.

He et al. (2007) built on this idea as they studied the emergence of team cognition on software projects. Software developers cannot rely strictly on their coding knowledge to be effective on teams. Developers must also rely on meta-knowledge concerning team composition, especially in areas where the developer needs assistance or lacks the necessary knowledge to complete tasks. For instance, developers may have specific specialties to complement one another in a project team. One developer may have expertise in user interface development, while another may specialize in database processing. And, even though these areas of expertise are distinct, developers on the team overall must share an understanding of the "procedures, sequences, and actions (p. 265)" required to complete the work. Organizations must emphasize the necessity of good team formation – when team members have a solid background of what each member knows, the efficiency of eliciting information from one another increases. The way teams communicate with one another may also influence the emergence of expertise location awareness and shared understanding. For example, teams which utilized face to face contact over emails developed stronger levels of team cognition. In summary, a developer must be able to learn about what their colleagues know, and have interactive engagements with them to maximize their contribution to the team.

Rasch and Tosi (1992) adapted expectancy theory, goal-setting theory, and individual characteristics to study antecedents of individual software development performance. Expectancy theory (Vroom) considers performance as a function of ability, effort, and role ambiguity. Goal-setting theory (Locke and Lantham) considers goal specificity as an important part in reducing role ambiguity, and increasing goal difficulty can result in higher levels of effort. Individual characteristics such as self-esteem, need for achievement, and locus of control can also impact individual effort and performance. Rasch and Tosi (1992) found that individual effort was positively influenced by goal specificity and goal difficulty. Intellectual ability had the strongest direct influence on developer performance. This highlights two important issues for organizations. First, in terms of software development team member selection and configuration, firms must find ways to assess developer ability, which may be difficult considering the complexity of the work. Secondly, the way project goals are articulated and described to teams can have a strong influence on individual effort.

Deephouse et al. (1996) conducted an exploratory study to understand software development process influence on project performance. Processes such as design reviews, cross-functional

teams, and prototyping were assessed to determine overall impact. Planning was found to positively influence on meeting targets and project quality, while cross-functional teams were found to positively influence quality. Process training, environmental stability, user contact, design reviews, and prototyping did not have a significant influence on project outcomes. Although these findings came from a limited sample and were exploratory in nature, it is an example of an empirical study finding little impact of software development processes on performance.

Chilton et al. (2005) studied software developer job/ability fitness (Kristof) using adaption-innovation theory (Kirton). Adaption-innovation theory is centered on the idea that individuals have a cognitive style which can range on a continuum between highly adaptive to highly innovative. Adaptors prefer structure, rules, and few solutions. Innovators prefer many solutions, little structure, and are oriented towards the "big picture" (p. 197). When a person's cognitive style doesn't fit well with his/her job environment, additional energy is spent to cope, which can adversely impact performance. This theory was validated by Chilton et al. (2005), who found that software developers experiencing lack of fit with their job demands experienced more strain. This strain ultimately led to a negative influence on performance. Performance was appraised by managers, and measured based on three dimensions: soft skills, managerial skills, and technical skills. This illustrates the multidimensional nature of a software developer's skillset; not only must programmers be able to convert requirements into code, but they also must be diplomatic, present ideas to others, demonstrate empathy, listen carefully to others, and have leadership qualities.

Boh et al (2007) investigated the influence of learning curves on productivity at multiple levels of analysis (individual, group, and organization). The unit of analysis in the study was characterized as modification requests, or requests to add new functionality or repair a system defect. These modification requests were analyzed longitudinally to determine if experience within systems led to experiences that ultimately contributed to learning across different levels. Not surprisingly, individuals specializing in specific areas, working within the same system, became more productive as they learned about the system over time. Furthermore, experience in related systems (versus unrelated systems) appeared to transfer well across systems. Boh et al. (2007) also found, at the individual level, that developers learned from their counterparts. When developers are willing to help their colleagues, the benefits cascade beyond individuals to the group level. Interestingly, however, too much sharing and helping among a group may hinder organizational level productivity because teams may become entrenched in certain methods or approaches. Such an effect could result in a non-linear relationship, where helping one another may benefit groups and the organization at large to a certain extent, but may also result in a "too-much-of-a-good-thing" type of scenario.

Guinan et al (1998) investigated the influence of group processes on software development team performance during the requirements phase. Group processes (internally and externally oriented) can be influenced by behavioral or technical factors. They found that behavioral factors have a stronger influence on group processes than technical factors. Structured methods such as diagramming, data modeling, and joint application design (JAD) were not found to significantly impact team performance. Furthermore, behavioral factors (managerial involvement, team skill, and experience spread) were more influential on group processes than technical factors. Additionally, some of the feedback was observed from key informants: (1) Outcomes were better when teams were cohesive (2) it was a challenge to find the time to mentor new team members (3) people should be emphasized over tools (4) team members must be comfortable speaking to others they do not know and (5) it is often necessary to involve

others from outside the immediate project team. This illustrates the notion that a developer's skillset should expand beyond technical tasks.

Sarker and Sarker (2009) built on this concept and conducted an interpretive study to investigate agility in distributed software teams. As noted in Lee and Xia (2010), agility is the extent to which teams can respond effectively to rapid changes. To influence this agility, certain expectations emerged in terms of the development staff:

1) Adapt to rapid or unforeseen assignment to different teams (rotation).
2) Multiple skills/versatility (i.e. ability to perform both web and database development)
3) Use of communication technologies, source control management tools, project lifecycle tools.
4) Participation in frequent/short stand up meetings.
5) Work with individuals from different countries or in different time zones.

Based on Sarker and Sarker's (2009) findings, developers working in Agile environments are expected to have a blend of both technical and "soft" skills. Developers lacking the ability to work effectively with others, or who cannot succinctly articulate their progress during standups, may impede progress in Agile teams. Although technical skills are essential when converting system requirements into code, the languages and platforms shift and change over time.

Hardgrave et el. (2003) investigated software developer intentions to follow formal methodologies. Their model was based on the theories of technology acceptance model (TAM, Davis) and diffusion of innovation (DOI, Rogers). The antecedents to intentions included individual and organizationally related factors including perceived usefulness, complexity, social pressure, compatibility (like fitness), and perceived organizational mandate (degree to which individual felt the organization was mandating methodology use through formal policy). Not surprisingly, perceived usefulness of a methodology was a significant and positive influence on intentions to follow a methodology. The strongest influences on perceived usefulness were complexity (unfavorable influence on perceived usefulness) and compatibility; these influences were even stronger than organizational mandates. Overall, this illustrates the role individuals play in methodological adherence; the need for developers to buy into the methodological practices handed down to project teams is critical. If developers believe a methodology is requiring too much mental effort or is difficult to follow, they may not follow standards/guidelines. If developers feel that the methodology is compatible with work style, they may be more willing to adhere to standards/guidelines.

Ply et al. (2012) investigated the interaction between software process maturity, control modes (outcome vs. behavioral), and IS employee attitudes (role ambiguity, role conflict, work overload, professional efficacy, job satisfaction, and cynicism). Their study was based on the Capability Maturity Model (CMM), which was developed by the Software Engineering Institute (SEI) in the late 1980's and early 1990's. CMM is not a specific methodology like Agile per say, but rather a reference model which provides specific guidelines to organizational software processes. These processes address various areas including requirements management, performance management, service management, project management, and organizational development/readiness. The degree to which firms adhere to the prescriptions set forth in CMM is rated in levels. For instance, level 1 represents no formal processes, whereas level means processes have been fully established and are in optimization mode (see Ply et al. (2012) pp. 605-606 or a good summary of each CMM level). One of the key findings in this study was that IS professionals working in CMM level 3 organizations reported lower levels of professional efficacy and job satisfaction than their CMM level 1 counterparts. Level 5 IS professionals also

reported higher levels of cynicism than their lower level counterparts. Overall, these results seem to suggest a "dark side" as the rigor and standards of software processes increase.

Agile methods often call for cross-functional teams who can shift roles and take on different responsibilities. Developers may need to modify or change code that they did not originally create. It can be argued that this type of software change is more difficult than novel development because it requires not only an understanding of pre-written code, but also an understanding of original intent of the software in question. Therefore, developers in a maintenance or bug-fix setting require dual-task problem solving abilities. Shaft and Vessey (2006) conducted an experiment which compared difference in modification performance based on (a) familiarity of the software and (b) the type of modification (control flow modification, or ordering/sequencing of action vs. function modifications, or main goals/objectives of the software). They found that program comprehension (understanding of previously written software, syntax, programming constructs) does not always lead to higher modification performance, especially when a lack of cognitive fit exists between the developer's mental representation of the code and the type of modification required. This illustrates the importance of team configurations, requirements, documentation, and training when projects reach a maintenance/bug-fix/modification mode. Developers who are strictly versed in programming/syntax may not necessarily perform well on modification tasks. In certain contexts, they will also need a degree of familiarity with the application domain itself, which they may not have had prior to the task. Overall, their findings illustrate the nature of development work and how it spans beyond simply knowing how to write code.

Due to the nature of the work, developers are at risk of experiencing career exhaustion over the long run. Constant shifts and changes in demands from coworkers and customers can leave developers feeling burned out. Not surprisingly, Armstrong et al. (2015) found that that when IS professionals perceived higher levels of workload demands, the likelihood of feeling "career exhaustion" increased. This type of career exhaustion, which is conceptually linked to burnout, would automatically occur if the only factor taken into consideration was perceived workload. Fortunately, favorable individual level job appraisals are still possible, even when workloads are heavy. Armstrong et al. (2015) illustrated that when IS professionals felt they were treated fairly and in control of their career, they were less likely to perceive this type of exhaustion. Furthermore, methodologies encouraging self-led teams and autonomy can encourage developers to experience less career exhaustion, and potentially hedge against burnout. Whether this holds true under different software methodologies remains a question.

To be effective, software developers are required to be sociotechnical experts. Software developers must be able to fully participate in project meetings, assist with planning, provide information or help to colleagues, be aware of teammate variance in expertise, and adhere to rigorous and fast-paced methodologies. From a technical perspective, software developers must work with ill-structured information, create/review/modify code, and stay on pace with new or emerging technologies. Because the role of a developer covers so many areas, outcomes have the potential to benefit not only individual appraisals (both self and supervisors/colleagues), but also project outcomes and the organization at large. Job satisfaction, while linked to favorable individual outcomes such as performance, is volatile to change and can vary depending on several contextual factors. This may explain why satisfaction-based studies have led to mixed findings in software methodology research (Ply et al. 2012, p. 610). Therefore, satisfaction may not be rigorous or stable enough to capture the essence of complex links between developer work configurations, the developer's relationship with his/her job, and the outcomes emerging from those links. This is especially true in Agile environments, where the work may shift rapidly on a day to day basis. According to Maslach et

al. (2001), “Job satisfaction is the extent to which work is a source of need fulfillment and contentment, or a means of freeing employees from hassles or dissatisfiers; it does not encompass the person’s relationship with the work itself. Job involvement is similar to the involvement aspect of engagement with work, but does not include the energy and effectiveness dimensions. Thus, engagement provides a more complex and thorough perspective on an individual’s relationship with work (p. 416).” Engagement, in turn, can be linked to stable behaviors not only described as “in role”, but also those behaviors which may have broader organizational benefits.

Job Engagement

While job satisfaction captures an individual’s overall job attitude, job engagement captures persistent and dimensions that are highly relevant in complex and demanding jobs like software development. Job, or work engagement, is defined as a “positive, fulfilling work-related state of mind that is characterized by vigor, dedication, and absorption (Schaufeli & Bakker, 2006, p. 702; Schaufeli et al. 2002). Job engagement captures a level of dedication an employee has towards his or her job (Owens et al. 2016). Recent interest concerning job engagement in industry is motivating further research on this characteristic (Eldor and Harpaz. 2016). Job engagement is an important part of assessing employee performance, and can foster organizational effectiveness. Although engagement is considered non-volatile, research has shown some within person variation may occur day to day (Sonnentag 2003). According to James et al. (2011), employers are becoming more interested in assessing employee engagement; there are economic costs when engagement is not occurring (i.e. burnout or sub-optimal individual contributions), and having engaged employees has become an important organizational goal (pp. 176-177). An engaged employee may be able to cope with pressure and demands more effectively. Organizations who foster resources which encourage higher levels of engagement can position themselves to meet the growing business demands in a complex and dynamic economy.

There are two main views of job engagement in organizational research: (1) as the opposite of burnout view and (2) as the psychological appraisal view (Byrne et al. 2016). The former is based on Maslach et al., and the latter is based on Kahn. Studies such as Maslach and Leiter (2009) regard engagement on a continuum, where individuals expressing lower levels of burnout are said to be more engaged. Studies such as Rich et al. (2010) regard engagement as the investment of one’s complete self in their work. Kahn (1990) described personal work engagement as the immersion of one’s physical, cognitive, and emotional self into one’s job. The degree to which an individual expresses these dimensions can vary, and are favorable in “appropriate conditions (Kahn 1990, p. 700.).” Kahn (1990) also described antecedents which lead to favorable levels of job engagement: psychological safety, psychological meaningfulness, and psychological availability (Zhong et al. 1995, p. 825). Project management practices in Agile environments may encourage these conditions. For instance, a developer’s psychological safety and availability may be cultivated in standup meetings or retrospectives, where team members collectively share progress or roadblocks. Iterative planning may invoke feelings of meaningfulness, showing progress at earlier intervals throughout a project. Extant research on job engagement has shown negative correlations with burnout, although more recent studies have criticized this opposite-of-burnout view (Byrne et al. 2016). The dimensions of job engagement are traditionally characterized as follows:

1) ***Vigor*** is associated with high levels of mental resilience, especially when challenges arise. This type of mental orientation can be beneficial when code is experiencing unit testing errors,

or when there is difficulty eliciting necessary system feature requirements from non-technical customers.

2) ***Dedication***, which captures a level of pride and enthusiasm, can be of great importance when sharing status updates in team meetings, assisting requirements analysts, working extra hours, or working in collaborative pairs.

3) ***Absorption*** is being fully concentrated and engrossed in work, which can be extremely beneficial when additional effort or work hours are required to meet milestones.

Although these dimensions are conceptually distinct from job satisfaction, more work has been encouraged to empirically differentiate and distinguish job engagement from job satisfaction (Wefald and Downey 2008).

Using data from sales personnel and their subordinates, Haynie et al. (2016) hypothesized that job engagement mediated the relationship between perceptions of organizational justice (fairness) and task performance, organizational citizenship behaviors, and job satisfaction. Rich et al.'s (2010) scale was chosen to measure job engagement because other measures have been criticized because they do not capture Kahn's (1990) original dimensions. OCB's were measured using Lee and Allen's (2002) 16 item instrument. Distributive justice (fairness perceptions oriented towards outcomes) was found to be a significant predictor in this relationship, which aligns with prior theory stating that distributive justice prompts positive affect (engagement) towards work outcomes.

Using a multi-level model, Zhong et al. (2015) investigated how employee role behaviors are impacted by job engagement, high performance human resource (HR) practices, cultural factors, and perceived organizational support (POS). Examples of high-performance HR examples include: selective staffing, internal mobility, employment security, clear job descriptions, incentive rewards, and results-oriented appraisals. The authors found that POS partially mediated the relationship between high performance HR practices and employee engagement. In other words, an organization can use HR practices to cultivate the extent to which an employee believes the organization supports them. This, in turn, leads to more favorable levels of employee engagement. One interesting finding in this study, however, is that job engagement had no significant relationship on extra-role (OCB) behaviors. One explanation provided was that more engaged employees may be prioritizing in-role behaviors over extra-role behaviors. However, they also encouraged future research specifically address those relationships further.

According to Nahrgang et al. (2011), "There are many job demands and resources present in the working environment, and it is important to understand which job demands deplete mental and physical resources the most and which job resources are the most motivating (p. 72)." One of the mechanisms through which this type of motivation can be realized is through job engagement. Engagement is a measure of involvement, participation, and communication – three areas which are critical in Agile development teams.

James et al. (2011) compared the extent of job engagement and its antecedents across different age groups. The large sample (N=8433) consisted of all ages did not distinguish based on job title. Engagement was measured using a custom scale developed for company. The antecedents to engagement were conceptualized as supervisor support and recognition, schedule satisfaction, career development and promotion, and job clarity. Control variables included gender, education level, hourly vs. exempt status, full vs. part time, and marital status. Their analysis determined that older workers demonstrated higher levels of engagement than

younger workers. Furthermore, engagement was influenced more favorably by supervisor support and recognition in younger workers, while younger workers were more influenced by career development and promotion. Job clarity, which measured tool / resource availability and expectations, was a strong influence on engagement for both younger and older workers. This illustrates that engaged employees must have a clear understanding on what is expected of them, and that they have the tools necessary to do their jobs. In software development environments, facilitating conditions such as standups and iterative planning methods can continuously address these areas to ensure what is expected is articulated, requirements are clear, and that roadblocks are addressed.

Wu et al. (2016) conducted a time-lag study to address mixed findings surrounding workplace ostracism and employee engagement. Workplace ostracism is defined as the extent to which an employee feels he or she is being excluded or ignored (p. 362). Ostracized employees may feel more motivated to engage in acceptance-seeking behaviors benefiting other individuals as well as the organization. On the other hand, ostracized employees may be discouraged, and feel less motivated to engage in such behaviors. In their model, Wu et al. (2016) hypothesized that organizational identification (incorporating organization into mental self-schema) mediated the relationship between workplace ostracism and organizational citizenship behavior. Job engagement at period 2 (after 10 weeks), was found to have significant, negative correlations with workplace ostracism, and significant, positive correlations with organizational identification, organization based self-esteem, and felt obligation towards the organization. This illustrates that employees who feel more included socially with their peers are more likely to feel engaged in their work they do. Engaged employees are also more likely to engage in prosocial behaviors. Software development practices such standups, pairing, retrospectives, and iteration planning meetings can give each team member an opportunity to participate, share, and collaborate with their peers. In turn, these practices may lower the possibility that a team member feels excluded or left out.

Wang et al. (2014) investigated organizational justice, job insecurity, and job engagement's effects on job performance. Job insecurity is the uncertainty one feels towards the continuity of his/her employment. If an employee feels insecure in their job, their engagement may suffer, which can lead to lower levels of performance and higher economic costs to the organization. In a dynamic and shifting economy, employees must feel secure enough in their job so that they remain engaged and productive. Uncertainty management theory (UMT) research has shown that perceptions of fairness help individuals cope under conditions of uncertainty. Collecting data at multiple periods, Wang et al. (2014) determined that job (work) engagement mediated the relationship between job insecurity and job performance. This was especially true when insecurity interacted with lower levels of perceived organizational justice.

Shaufeli et al. (2009) used the Job Demands-Resources (JD-R) to study the influence of burnout, engagement, job resources, and job demands on absenteeism. According to the authors, "the Job Demands–Resources (JD-R) model is a heuristic and parsimonious model that specifies how job strain (burnout) and betterment (work engagement) may be produced by two specific sets of working conditions that can be found in every organizational context: job demands and job resources (p. 894)." Job demands are the aspects of the job requiring effort (could be physical/social/organizational), and job resources are the things which reduce that effort, help achieve goals, and/or encourage growth/development. Examples of job demands include work overload, emotional demands, and work-home interference. Examples of job resources include social support from supervisors/co-workers, feedback, coaching, autonomy, task variety, and training. JD-R research has shown that job resources can help employees remain dedicated to their efforts and can reduce strain and burnout. Shaufeli et al. (2009)

hypothesized that, over time (1 year), increases in job resources will predict future work (job) engagement. The authors found that when resources increase, job engagement tends to increase as well. Subsequently, higher levels of work engagement negatively influenced voluntary absenteeism. Furthermore, they found that organizations, to foster higher levels of engagement, organizations should focus on increases in resources, rather than on reduction in demands. Employees who are working under conditions of high demand can remain engaged if enough job resources are available.

Petrou et al. (2012) studied the effect of job autonomy, work pressure, and job crafting on job engagement. Job crafting is "proactive employee behavior consisting of seeking resources, seeking challenges, and reducing demands (p. 1122)." Asking a colleague for help is an example of seeking resources. Looking for a new task or taking on more responsibilities are examples of seeking challenges. Procrastination or task avoidance are examples of resource reduction. Resource reduction, in turn, can be considered an active behavior when employed as a coping strategy for job demands. Petrou et al. (2012) hypothesized, at the day level, that seeking resources and challenges positively influence job engagement, while demand reduction negatively influences job engagement. On days when employees sought challenges or reduced demands, they were more engaged. Individual crafting behaviors were found to differ day to day. When higher levels of employee work pressure and autonomy were perceived, employees sought more resources.

Sonnentag (2003) studied the effect of recovery on job engagement and proactive behaviors. Recovery during leisure time (nights and weekends) can be an important consideration for maintaining well-being and favorable levels of performance. The way individuals recover when they are away from work can have an impact on how they perform when they return to work. When employees recover properly, Sonnentag (2003) hypothesized higher levels of work engagement and higher levels of proactive behaviors. Proactive behaviors were conceptualized as volitional and self-improving, and items were worded so these behaviors could be measured as traits and as daily behaviors (personal initiative and pursuit of learning). A multi-level analysis nested daily appraisal within the person, so that the relationship between day to day variances and the overall person could be evaluated. Work engagement was found to mediate the relationship between recovery and proactive behaviors. The study also showed how day to day activities can introduce variability into work engagement and proactive behaviors. Organizations fostering daily and consistent methods which cultivate an engaging environment can protect against negative variations. In software development environments, daily standups and frequent face to face collaboration have the potential to provide these affordances.

Byrne et al. (2016) evaluated two common measures of job engagement: the Utrecht Work Engagement Scale (UWES, Shaufeli et al. 2002) and the Job Engagement Scale (JES, Rich et al. 2010). The UWES is based on the conceptualization of engagement as the opposite of burnout. It is a reverse-coded version of the Maslach Burnout Inventory (MBI). The JES is based on Kahn's conceptualization of engagement, and captures dimensions of physical, emotional (affective), and cognitive assessments. Byrne et al. (2016) determined that the UWES captures a broader, more general domain of job engagement. Job engagement, when measured with the UWES, was strongly correlated with stress (-), job performance (+), strain (-), organizational commitment (+), job commitment (+), psychological availability (+), and burnout (-). However, this may be due to UWES' redundancy and confounding effects. The JES was found to demonstrate "less overlap with associated attitudes (p. 1218)," and more distinctiveness in the nomological network of engagement.

Saks (2006) describes the concept of job engagement in the context of related constructs such as organizational citizenship behavior (OCB), job involvement, and organizational commitment. Organizational commitment refers to one's attachment to an organization. As stated by Saks (2006), "engagement is not an attitude, it is the degree to which an individual is attentive and absorbed in the performance of their roles (p. 602)." Job involvement is tied to self-image and focused only on cognitions concerning the need satisfying abilities of the job. Job engagement, on the other hand, measures cognition, emotions, and behaviors. Saks determined that job characteristics and perceived organizational support were significant predictors of job engagement. Job engagement was also found to significantly influence outcomes such as job satisfaction, organizational commitment, intention to quit, and organizational citizenship behaviors oriented towards the organization (OCBO's). Job engagement was measured with developed scales, rather than the UWES or the JES. See Hallberg and Shaufeli (2006) for a similar study which also established the distinctiveness of job engagement from job involvement and organizational commitment.

Organizational Citizenship Behaviors (OCB's)

Individual contributor performance can be assessed based on three dimensions – (1) in role behaviors (expected tasks), (2) behaviors which promote the performance of others, and (3) behaviors which promote the effectiveness of the organization. Organizational citizenship behavior (OCB) theory emphasizes the relationships between these dimensions of performance, along with their antecedents and consequences (Williams and Anderson 1991). According to Dekas et al. (2013), "OCBs are crucial in the knowledge economy, where roles are less defined and the external environment is rapidly evolving. (p. 220)." OCB's are salient to IS researchers and practitioners because they can have a favorable influence on knowledge sharing, software quality, and customer service (Dekas et al. 2013; Chih-Ching et al. 2014).

Organ (1989) conceptualized the "classic" dimensions of OCB as follows: (Yoon 2008; Chou et al. 2013, p. 106): (1) **Altruism**, or helping behaviors, (2) **Conscientiousness**, or going beyond organizational standards (3) **Courtesy**, or action to prevent problems. (4) **Sportsmanship**, or positive thinking, or acceptance of minor impositions) and (5) **Civic virtue**, or constructive and responsible involvement in organizational governance. These dimensions emerge at an individual level, but could (a) be influenced by group/organizational level antecedents and have (b) group/organizational level outcomes. As described by Schnake and Dumler (2003), "The OCB construct itself is a multi-level construct. Mixed-level antecedents predict the extent to which individuals engage in OCB; however, theoretically it is OCB in the aggregate, and not individual instances of OCB, which impact organizational effectiveness (p. 295)." Beyond organizational effectiveness (Podsakoff et al. 1997), OCB's also depend on cultural aspects (Motowidlo 2000; Perlow and Weeks 2002), and have an impact on overall productivity.

OCB's can improve organizational effectiveness, but may have negative consequences as well. If an individual contributor is spending too much time helping others, the individual's in role productivity may suffer. OCB's may lead to burnout if organizations are not judicious in terms of keeping promises (psychological contracts) and providing the right level of emotional support and gratitude (Brown and Roloff 2015). Co-workers may construe the demonstration of others' OCB's as self-serving, which could have negative impacts on job satisfaction (Tepper et al. 2004). OCB's are instrumental to performance appraisal and promotion, but individual behaviors could decrease once the promotion is gained (Hui et al. 2000). OCB's may also increase the risks of emotional exhaustion and work-family conflict, especially in with higher level task performers. (Deery et al. 2016).

The impact of OCB's should be appropriately weighed in parallel with the extent an individual is performing his/her actual expected job duties. According to Van Dyne et al. (1995), an extra-role behavior is discretionary, goes beyond delineated role expectations, and benefits the organization. For instance, a developer mentoring a new employee, when the developer is not instructed or expected to do so, would be considered an extra-role behavior (Ang and Slaughter 2001). OCB's are not enforceable – they are affiliative, promotive, may be unrewarded, and support the effective functioning of an organization (Organ 1997). At the outset, OCB's were devised to address how job satisfaction influences extra-role behaviors. Organizational research using OCB theory continued to evolve, which gave rise to construct ambiguity, confusion, and conceptual bleed-over across terms to describe helping behavior, such as extra-role behavior and contextual performance (Borman and Motowidlo 1993). Although both Motowidlo and Organ both de-emphasized the importance of labeling, Motowidlo (2000) provided some additional conceptual guidance for research: Extra-role behaviors are discretionary and intended to benefit the organization. OCB's are discretionary, but also lack formal recognition by reward systems, and in aggregate promote the effective functioning of the organization. Contextual performance is concerned with enhancements to the social and psychological context of work, as well as antecedents and consequences of task performance. As research in OCB's progressed, Organ (1997) also considered the distinction between in role and extra role behaviors as having less utility. Mackenzie et al. (1998), however, still regarded these distinctions as important (p. 88). In summary, in role and extra role behaviors lie somewhere on a continuum, and concrete distinctions between the two is difficult to recognize universally (Podsakoff et al. 2000, p. 549). As will be seen below, OCBs have also been found to influence promotion appraisals, which conflicts with "unrewarding" characterizations.

Vandyne et al. (1995) noted the ambiguity of several different constructs describing extra role behaviors in organizational research. Furthermore, it is difficult to distinguish between in role and extra role behaviors because assessments depend on who is observing the behavior, relative differences between employees, and the time frame in which individuals are being observed. Additionally, a lack of construct clarity between different types of extra-role, prosocial behavior has led to ambiguity in OCB research. Vandyne et al. (1995) subsequently characterized the uniqueness of OCB with the following arguments:

(1) OCBs are a specific type of extra role prosocial behavior with distinct characteristics.
(2) OCBs do not include prosocial organizational behaviors can be disruptive (like whistle blowing)
(3) OCBs are generally compliance-based, promotive, and affiliative.
(4) The civic virtue dimension of OCBs is constrained and fully immersed in organizational politics.
(5) OCBs may include constructive recommendations for change.
(6) Extra role behaviors like OCB should be studied specifically rather than as a generic prosocial behavior construct.

Arda et al. (2017, p. 17-18) provide a longer list of OCB dimensions operationalized in organizational research – these additional dimensions include loyalty, obedience, and participation (Bolino et al. 2002; Graham 1991). Graham's (1989) dimensions are (1) interpersonal helping (helping coworkers) (2) individual initiative (communications to others/group to help group performance (3) personal industry (performance of tasks above and beyond call of duty) and (4) loyal boosterism (promotion of organizational image to outsiders (Moorman et al. 1998). Dekas et al. (2013), through a scale development exercise at Google, revealed OCB dimensions which may be more suitable for knowledge workers (OCB-KW scale), including helping, voice, civic virtue, employee sustainability, and social participation. Williams

and Anderson (1991) adapted Organ's (1988) dimensions and developed scales for OCB-I's (OCB's directed at individuals) and OCB-O's (OCB's directed at the organization). Williams and Anderson (1991) illustrated evidence supporting these unique dimensions of performance – in role behaviors, OCBI's, and OCBO's. OCBI's (Individual) benefit individuals (helping a coworker), while OCBO's (organization) are organizationally focused (adhering to informal organizational procedures. Podsakoff et al. (1990) developed a 24-item scale for OCB's which also capture Organ's (1988) original dimensions.

OCB's may be frequent, infrequent, occur spontaneously, and may arise in unforeseen situations (Smith et al. 1983). Specific examples of OCB's include, "helping co-workers, communicating new and critical information, maintaining a conscientious attitude toward the work environment, actively participating in decision processes and discussions, and refraining from complaining about minor irritants (Yen et al. 2008, p. 395)." OCB's may go unnoticed by superiors but can still result in significant increased task performance (Arda et al. 2017) and other organizational gains, including "resource transformations, innovativeness, and adaptability (Organ 1988; Williams and Anderson 1991, p. 601)." Circumstances requiring creative, fast, and context-specific effort may require unexpected and often unrewarded solutions. According to OCB's seminal researchers (Smith, Organ, and Near 1983), these behaviors cannot be explained by the normal day-to-day motivational bases of job duties. The reason for this, according to Organ (1988), is because OCB's are said to be performed without the promise of rewards. In a study conducted by Bruque et al. (2016), OCB's were found to positively influence individual outcomes such as adaptation to change and task performance. Therefore, software development, which is driven by organizational needs for innovation, task orientation, and the ability to be flexible is a suitable context with which to apply the lens of OCB.

The determination of whether a behavior is in role vs. extra role may be subjective and partially dependent on social construction (Morrison 1994). Because perceptions of job roles and their boundaries can vary widely among individuals and organizations, the OCB construct has undergone a great deal of scrutiny and retrospection. Employees and supervisors may differ on whether they categorize a behavior as in role vs. extra role. The same behavior, over time, may be categorized differently as well.

Shin and Choi (2014) integrated person-environment fit theory (Kristof 1996) and regulatory focus theory (Higgins 1997, 1998) with OCB. In their model, OCB was operationalized using Dewitt and Dewett and Denisi's (2007) typology of "change OCB and "maintenance OCB." Maintenance OCB's, which can be individually or organizationally oriented, are concerned with the status quo and existing relationships. Change OCB's are focused on are all organizationally focused and are oriented towards work methods, policies, and procedures (Shin and Choi 2014 , p.3). Regulatory focus theory states that individuals with promotive self-regulation approach positive outcomes with eagerness, risk taking, and achievement orientation. On the other hand, individuals with preventive self-regulation approach objectives more vigilantly, conservatively, and with a tendency to avoid negative outcomes. Person-environment fit theory says that employees provide more value to the organization when their individual preferences are congruent with the characteristics of the work environment. Their model demonstrated that higher levels of congruency between leader and subordinate prevention focus lead to higher levels of subordinates' maintenance OCB's. This same congruence effect was lacking for increased levels of change OCB.

Podsakoff and Mackenzie (1997) provided an overview of OCBs and empirical evidence in research demonstrating links to organizational effectiveness. OCB's can help in "'lubricating' the social machinery of the organization, reducing friction, and/or increasing efficiency (p. 135).".

As indicated on p. 156, the following reasons describe why OCBs influence work group and/or organizational performance: (1) enhancement to coworker productivity, (2) enhancement to managerial productivity (3) freeing up resources for more productive purposes (4) reduction in the need to devote scarce resources (5) effective means of coordinating activities (6) enhance ability to attract/retain the right people (7) enhancement to stability of organizational performance and (8) enhancement to ability to adapt to environmental changes.

Mackenzie et al. (1998) evaluated the antecedents and consequences of in role and extra role behaviors, specifically in salespeople. Extra role behaviors are important to assess because they are "linked empirically with organizational performance and success (p. 95)." There is also value in distinguishing between in role and extra role behaviors for salespeople because: (1) managers take both into account in performance appraisals (2) both have implications for organizational performance (3) the two types of performance are believed to have different antecedents and consequences (IE in-role performance influences satisfaction, and satisfaction influences extra role behaviors). Extra role behaviors were measured in this study using a Podsakoff and Mackenzie (1994) instrument, which was developed based on Organ's OCB dimensions of altruism, sportsmanship, and civic virtue, and then aggregated into a composite score. In their model, role ambiguity and role conflict influence in role performance. In role performance and job satisfaction negatively influenced turnover. Extra role performance was a consequence of organizational commitment and job satisfaction. These findings helped confirm the direction of causality between performance and satisfaction. It also helped confirm that in role and extra roles are distinguishable from one another and may have unique characterizations in a nomological network.

Podsakoff et al. (2000) conducted a review of findings in prior OCB research (antecedents, consequences) and provided guidelines for future research. Antecedents to OCB dimensions in research were categorized as individual differences/ability, task characteristics, organizational characteristics, and leadership behaviors. In terms of all 5 of Organ's (1988) OCB dimensions, the following correlated favorably and significantly based on the authors' analysis: Task feedback, intrinsically satisfying tasks group cohesiveness, transformational leadership, and supportive leadership. In terms of consequences, OCB's have been linked to objective measures of organizational performance, such as index of sales, product quality, sales quotas, revenue, and customer satisfaction (p. 547). Research in OCB's is most useful when the antecedents and consequences to in and extra role behaviors can be distinguished. Otherwise, organizations would not know which mechanisms or "levers" are influencing on type of behavior over the other. As far as future research directions, Podsakoff et al. (2000) recommend the following

1) Identify unique antecedents and consequences of different forms of OCB.
2) Include multiple forms of citizenship behavior and statistically test for differences.
3) Further research the influence of task characteristics and leadership behaviors.
4) Further research the influence of OCBs on unit level performance and possible mediators between OCBs and performance.
5) Work group or organizational level performance outcome variables deriving from OCB should be investigated.
6) Articulate and test the effects of cross-cultural differences.
7) Mitigate against common method variance (single source bias) and issues concerning direction of causality (experiments or longitudinal designs).

Podsakoff et al. (2009), in a more comprehensive meta-analysis, tested hypotheses of OCB consequences (unit and individual level), along with moderators between OCBs and

performance. OCBs were found to positively influence ratings of performance and reward allocation; they were also found to negatively influence turnover intentions, actual turnover, and absenteeism. Organizational outcomes that were positively influenced by OCBs included productivity, efficiency, productivity, and customer satisfaction. When performance was self-reported, the influence of OCB's on outcomes was stronger. This illustrates a moderating effect related to research design. Organizations fostering and encouraging OCBs are more likely to realize gains in organizational performance. Furthermore, employees who were found to be rated higher in OCBs tended to be rated higher in task performance as well. The distinction between OCB-I and OCB-O was not found to be meaningful in terms of individual level differences, however, this may be due inconsistencies in post hoc categorizations.

Ang and Slaughter (2001) investigated the differences between permanent and contract software developers in the following areas: work attitudes, work behaviors (in-role/extra-role), and work performance. In-role behaviors, which are expected and rewarded, can cause significant impact when they are not fulfilled by well-paid employees like software developers. Extra-role behaviors, or those considered voluntary and beyond expected job duties, are essential to projects and organizations at a whole. The consequences of not carrying out extra or in-role behaviors may be different, but when a developer is not assisting others, filling in a colleague who was absent, or volunteering to take on some extra duties, there could be noticeable effect on project outcomes. In their study, contractors were found to demonstrate the same degree of in role behaviors as permanent employees, but expectedly less extra-role behaviors. Furthermore, there was a high degree of positive correlation between in-role and extra-role behaviors. Therefore, organizations with permanently employed inhouse developers have an opportunity to harness residual benefits beyond what is simply and explicitly expected from them on a day to day basis.

Cui (2017) investigated the influence of personality dimensions (openness to experience, conscientiousness, extraversion, agreeableness, neuroticism) on IS professional knowledge sharing behaviors. More specifically, knowledge sharing was characterized as "in role" (the extent to which sharing knowledge was expected) and "extra role" (sharing more knowledge than what would be expected in the individual's day to day activities). Extraversion lacked significant influence on any knowledge sharing behaviors. Openness to experience strongly influenced extra role knowledge sharing, while agreeableness strongly influences both in role and extra role knowledge sharing. Therefore, individuals who are hired based on (a) their willingness to remain flexible to change and (b) their ability to collaborate well with others may share knowledge above and beyond what is normally expected. This, in turn, can lead to positive effects on team cohesion and ultimately better team performance.

O'Reilly and Chatman (1986) investigated the influence of organizational commitment (compliance, identification, and internalization) on prosocial behaviors. The dependent variables in the study were in-role and extra-role behaviors. In-role behaviors were operationalized as items measuring working full shifts, completing assignments on time, and compliance with rules and regulations. Extra role behaviors were operationalized as items measuring volunteering, making suggestions, attending functions that were not required, and participating in planning / organization of social events. Based on the results of two separate studies, O'Reilly and Chatman (1986) concluded that extra role behaviors were a function of identification and internalization. In other words, employees who simply follow the rules are not likely to engage in affiliate, prosocial behavior. They stated that the "motivational basis for extra-role behaviors is likely to require more than simple compliance. A failure to develop this psychological attachment among members may require the organization to bear increased costs associated with more detailed and sophisticated control systems (p. 493)."

Rioux and Penner (2001) investigated the role of personal motives and the demonstration of OCBs. The authors argued that there was little research available which explained the motives for engaging in OCBs. Because OCB measures are sensitive to the rater (self vs. peer vs. supervisor), responses from all three sources were obtained. A scale was developed to measure citizenship motives, comprised of three dimensions: organizational concern, prosocial values (wanting to engage with and help others), and impression management (how one looks to co-workers). The authors hypothesized that prosocial motives would account for significant variance in OCBs. Prosocial motives accounted for significant variance in altruism, courtesy, and civic virtue. Organizational concern accounted for significant, favorable variance in in civic virtue. These relationships were evident regardless of the source of OCB ratings. In summary, Rioux and Penner (2001) determined that personal motives play a part in the demonstration of OCBs.

Eldor and Harpaz (2016) studied the influence of perceived learning climate on employee engagement and extra role behavior performance. Extra role behaviors were conceptualized as proactivity, knowledge sharing, creativity, and adaptivity. If employees feel that the organization supports the creation, acquisition, and transfer of knowledge, Eldor and Harpaz (2016) argued that employees will feel more engaged and ultimately demonstrate more proactive and volitional knowledge sharing and creativity. This is because research has shown that employees with favorable levels of job engagement demonstrate higher levels of arousal and activation. To understand delineate the influence of engagement from related constructs such as job satisfaction and job involvement, Eldor and Harpaz (2016) also tested the mediating influence of those constructs. They found that job engagement was the strongest mediator between perceived learning climate and extra role behaviors. This reinforces the idea that job engagement is “a different and more effective factor than more traditional explanations of job attitudes such as job satisfaction and job involvement (p. 228).” This type of engagement can be especially valuable on Agile development teams, where creative thinking, problem solving, and knowledge sharing behaviors can be critical to overall project success.

Diefendorff et al. (2002) studied the influence of job involvement, personality , work centrality, and gender on OCB’s. Job involvement is extent of one’s preoccupation, concern, and engagement with one’s job. Work centrality is the extent individual’s view work as a part of their life (importance belief). The authors found a significant interaction between job involvement and gender against two OCB dimensions: courtesy and sportsmanship. The influence of job involvement on courtesy and sportsmanship were stronger for females than males. Civic virtue was found to be the most closely related to job involvement.

Bachrach et al. (2006) studied the influence of task interdependence on group performance and OCB’s. According to the authors, “theory on self-managed work groups proposes that decision-making autonomy within a group may enhance motivation, and consequently, group performance (p. 1397).” Helping behaviors in low task interdependent groups may be construed as feedback for low performance. Furthermore, prior organizational research found contradictory results for OCB’s in groups having higher levels of task interdependence. Bachrach et al. (2006) hypothesized that task interdependence moderated the effects of helping behavior on group performance, where highly task interdependent groups would have more favorable performance, while low task interdependence groups would have more negative impacts on performance. OCB’s were operationalized as observations of group member helping. While high task interdependent groups demonstrated higher levels of helping behaviors and performance, the low task interdependent groups also demonstrated some lift in performance as well.

Allen and Rush (1998) investigated the relationship between employee performance judgments and OCBs. Employees demonstrating OCBs are may trigger "an affective response (p. 248)" in managers. This trigger leads to manager appraisals which are more favorable; the authors hypothesized that this "liking" response mediate the relationship between OCB's and overall evaluation and reward recommendations. Reward recommendations were directly and favorably influenced by OCB's, along with perceived affective commitment and causal motives. Drawing on social exchange theory, Aryee et al. (2002) determined that trust in supervisor mediated the relationship between distributive justice (i.e. perceptions of fair treatment) and both OCB-I's and OCB-O's. Bell and Manguc (2002) found that organizational identification (perceived oneness with the organization positively influenced all 5 dimensions of OCBs.

Chao-Min et al. (2015) evaluated citizenship behaviors in professional virtual communities (VC's). Virtual communities are online forums characterized by "self-organization, technology-mediated communication, weak ties among members, and the absence of formal reward systems (p. 948)." These online communities may bring together open source developers or programmers. They define virtual community citizenship behavior (VCCB) as behaviors which benefit the whole of the community. Agile software development, while more structured, have similar attributes, such as self-organization and technology-mediated communications. Chao-Min et al. (2015) operationalized individually-directed (VCCBI's) and community-directed (VCCBO's) citizenship behaviors, using Williams and Anderson's (1991) concepts. In their model, social (VC) attachment and satisfaction were hypothesized to be antecedents to VCCBI's and VCCBO's. The authors surveyed members of Programmers Club, a professional, online forum made up of IS programmers, designers, engineers, and analysts. The instrument used was pilot tested and then administered (N=196) to a Programming Club forum. Structural equation modeling revealed that satisfaction and virtual community attachment favorably influence VCCBI and VCCBO. Some of the manifest characteristics ultimately contributing to these higher levels of satisfaction and attachment included knowledge sharing efficacy, self-reflection learning, and social playfulness. This could be reflective of an Agile software development environment due to (a) the need to share knowledge among team members (b) the opportunity to contribute in planning meetings and retrospectives and (c) interact with group members and form relationships through stand-up meetings, pairing, or collaborative design.

Deng et al. (2015) conducted a mixed-method study to characterize customer-oriented OCB's of IS support staff. Customer-oriented OCB's were defined as employee discretionary behaviors in serving customer interests and needs not explicitly requested (p. 495)." In this study, the customer-oriented OCB were those demonstrated by personnel that were oriented towards a system's business users, specifically in the post-implementation phase. Customer-oriented OCB's differ from traditional OCB's because they're directed towards customers rather than colleagues on the same team. The organizational impact these OCB's have is inherent in "the dynamic knowledge transfer activities in IS post-implementation support (p. 491)." The coding scheme used a combination of previously identified customer-oriented OCB categories (education, anticipation, and justification from Rafaeli et al. (2002)) and newly developed ones (Personalization-business, personalization-technology). Using data from the organization's ticketing database and interviews, IS support/user interactions were analyzed, categorized, and evaluated across two different systems. Anticipation OCB's were found to be the most frequently employed, where IS support would provide anticipatory advice to users which may be useful to the user in the future, even though the knowledge was not specifically tied to the original ticket. The extent of which OCB's also varied as the post-implementation phase progressed.

To understand the demonstration of extra role performance, researchers should include measures of in role performance. This allows subsequent analysis to uncover characteristics that are unique to extra role behaviors. For example, Eisenberger measured in role performance using the following items adapted from Williams and Anderson (1991) : (1) Meets formal performance requirements of the job (2) fulfills responsibilities specified in job description (3) Performs tasks that are expected of him or her and (4) adequately completes assigned duties. Ang and Slaughter (2001) adapted scales from Vandyne and Lepine (1998) for in role behaviors, which include the following items: (This particular coworker) (1) fulfills the responsibilities specified in his/her job description (2) performs the tasks that are expected as part of the job (3) meets performance expectations and (4) adequately completes responsibilities. Extra-role behaviors such as OCBs are believed to go above and beyond these in role expectations. An individual demonstrating a lack of in role behaviors even in the presence of extra role behaviors would still be a concern, because that would imply that individual is not performing the basic duties for which they were hired.

THEORETICAL DEVELOPMENT/MODEL

The model being developed in this study has the potential to establish a link between software methodologies, job engagement, and individual software developer behaviors. Agile practices have emerged to improve software development productivity, versatility, and flexibility. Although practitioners continue to proliferate and employ these practices, research conclusions remain mixed in terms of whether the cost incurred by these methods truly outweigh their benefits. IS organizations, under continued pressure to meet project objectives, must also decide whether to wholly adopt modern methodologies like Agile, adopt alternative structured methods, or tailor processes specifically to address technical, environmental, or project challenges (Xu and Ramesh 2007). A clear and generalizable roadmap between processes and outcomes remains elusive. Paired programming has been linked to better performance on novel projects, but may incur other costs when novices are paired with experts (Dawande et al. 2008). Autonomous teams are thought to be more effective when responding to change, but may act obstructively when faced with unplanned changes (Lee and Xia 2010). Collaborative, iterative planning may help teams efficiently manage its backlog, but the technical work may still rely heavily on the oversight of a centralized technical expert, which can introduce bottlenecks (Kudaravalli et al.2017). Tripp et al. (2016) found favorable relationships between specific Agile practices and job satisfaction, but it remains unclear how greater satisfaction in this context amounts to higher levels of individual performance.

Agile practices are structured in a way so that team members can be versatile, cross-functional, contributive, self-reflective, and engaged. Standup meetings help team members communicate progress, roadblocks, and provide opportunities to “step up.” Burndown charts and other visualizations give team members the opportunity to identify work which may be lagging or failing to meet certain time/cost/quality objectives. Iterative delivery gives developers a chance to identify and work on critical slices of work, to deliver integrations and minimally viable products in an efficient and organized way. Retrospectives provide insights into improvement opportunities both individually and as a team. Therefore, Agile practices can be theorized to help developers feel more engaged, which in turn should influence his or her behaviors. This type of engagement captures deeper, abiding dimensions of employee perceptions (Maslach et al. 2001). Interest in engagement is gaining among employers, especially due to its economic implications – For example, engagement can influence lower levels of burnout, and higher levels of individual performance (James et al. 2011). Higher levels of job engagement have also been linked to behaviors with broader impacts at the organizational level. If the model in this study elicits significant results, it can serve as a benchmark for evaluating the efficacy of several

Agile practices. Conversely, if this model elicits insignificant results, then it can be said that Agile practices may have a negligible impact on the kinds of attitudes and behaviors managers should be encouraging. Prior research in job engagement has been linked to higher job performance (Wand et al. 2014), lower levels of absenteeism (Shaufeli et al. 2009), proactive behaviors (Sonnentag 2003), and organizational commitment (Saks 2006).

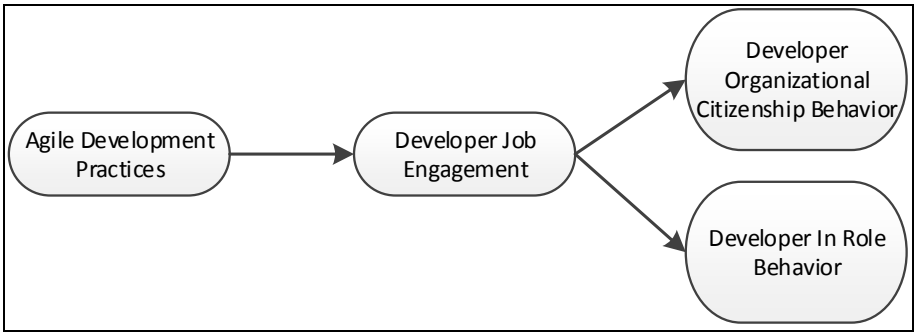
To begin, this model will propose that Agile practices influence higher levels of job engagement, which subsequently influences higher levels of in-role behaviors. In-role behaviors are considered foundational to the specific role or job function the employee was hired to perform. If Agile practices lead to favorable levels of job engagement, and higher levels of in role behaviors subsequently emerge, then managers should feel confident in their decision to adopt Agile practices.

H1: Job engagement mediates the relationship between Agile development practices and Software developer in role behaviors (IRBs).

In addition to performing expected job roles, employees may also engage in activities which are affiliative and promotive towards their co-workers and the overall organization. Such behaviors are usually voluntary in nature, and are "above and beyond" normal duties. This model proposal will adopt Organizational Citizenship Behaviors (OCB's) to characterize these extra-role behaviors. OCB's, according to Podsakoff and Mackenzie (1997), are believed to enhance organizational dimensions such as co-worker/managerial productivity, resource availability, and coordination efficacy. Employees demonstrating OCB's can be thought of as the all-stars who make the bench players around them perform at higher levels. If Agile practices lead to favorable levels of job engagement to the extent where OCB's emerge, then managers should feel confident in fostering those practices.

H2: Job engagement mediates the relationship between Agile development practices and Software developer organizational citizenship behaviors (OCBs).

Figure 1 - Research Model



METHODS

A professional sample of software developers and their supervisors will be needed for this study. A survey instrument will be administered using scales adapted from the following studies:

1) Tripp et al. (2016) – Agile project management practices which facilitate interactions with other employees – Burndown, iterative delivery, Stand ups, and Retrospectives. The intent of these items would be to measure the extent to which the individual perceives

his/her work group participates in these practices. These can be aggregated to a second order construct.
2) Rich et al. (2010) – Job engagement scale (JES), which is intended to capture the specific vigor, dedication, and absorption dimensions perceived by the developer in his/her work. The JES captures the original dimensions of job engagement proposed by Kahn (1990).
3) Lee and Allen (2002) – OCBO and OCBI scales commonly used in organizational research. These measures should be collected from supervisors to mitigate against single source bias. OCBO and OCBI's can be optionally aggregated to form a second order construct known as "OCB."
4) Williams and Anderson (1991) – In role behavior scales commonly used in organizational research. These measures should also be collected from supervisors.

Control variables used in the study will be age, job tenure, years of software development experience, and gender.

Model Measurement and Hypothesis Testing Options

Partial Least Squares (PLS) is an appropriate technique for theory-building models that employ small sample sizes and second-order factors (Gefen et al. 2000). PLS is also robust to data having non-normal distributions. In this theory-building study, job engagement will be measured as formative, second-order construct, and the sample size is not known. According to Gefen et al. (p. 9), a rule of thumb for PLS sample is to have at least 10 times the number of items in the most complex construct. Since job engagement has 18 items in total (sum of items in Vigor, Dedication, and Absorption), it is assumed a sample of at least 180 would be required for utilizing PLS in this study. Each Agile practice will be measured as its own first-order construct.

Wetzels et al. (2009) provides a set of guidelines for analyzing hierarchical (second-order) models using PLS, as originally suggested by Marcoulides and Sanders (2006). Included is a mediation analysis of direct and indirect effects. Those guidelines are summarized as follows:

1) Report the summary statistics and distributional properties of the manifest variables.
2) Specify a null model for the first order latent variables to assess psychometric properties.
3) Report the intercorrelations of the first order latent variables.
4) Calculate the composite scale reliability (CR) and average variance extracted (AVE)
    a. CR should be > than .80 and AVE should exceed .50 (per Fornell and Larcker 1981).
5) Calculate square root of AVE
    a. Should exceed the intercorrelations of construct "X" with other constructs in model
6) If the first-order model passes the criteria tests above, then construct model with the second-order factor (Job engagement) – this is by relating the to the block of the underlying latent variables. The remaining variables remain first-order constructs.
7) Calculate the CR and AVE of the second order model, and verify the criteria above for CR and AVE is still met.
8) If the second-order model passes the criteria tests above, now calculate the path coefficients in the model to test hypotheses.
    a. A test of direct and indirect effects can be conducted to assess whether job engagement mediates the relationship between Agile practices and the outcome variables. This involves measuring the direct effect of the antecedent (Agile practices) on the outcome variable (IRBs, OCBs). Then introduce the mediating

variable (Job engagement) to see if this direct effect changes significantly. Little to no change implies an absence of mediation. A modest change in the Beta coefficient implies partial mediation. A complete absence of a direct effect in favor of a direct effect implies full mediation.

b. Shrout and Bolger (2002) method can be used to test the standard error of the indirect effect.

9) Report all path coefficients (95% confidence interval) and p-values.
10) Introduce control variables to understand whether R^2 changes significantly.

DISCUSSION AND CONCLUSIONS

The following limitations are inherent in this proposal:

1) Cross-sectional research design may introduce concerns with direction of causality.
2) Convenience sampling will limit generalizability.
3) Agile software development measures are based on assessments of the group rather than the individual.
4) Task characteristics and specific performance outcomes are not measured.

Opportunities for Theoretical and Practical Contributions

Engaged employees successfully cope when faced with challenges and demands. Software development in Agile environments can be challenging, demanding, and complex. Understanding whether Agile practices contribute to engagement can unlock many opportunities for future research. Furthermore, employees who demonstrate citizenship behaviors are "good soldiers," and can help promote and cultivate higher levels of organizational effectiveness. A model of software developer job engagement and citizenship behavior can be the starting point for further research which (1) examine the variance in engagement/behaviors over time (2) integrate additional individual and organizational level factors and (3) measure specific individual, project, or organizational outcomes.

From a practical perspective, findings from this study can inform managers in terms of how Agile practices influence meaningful outcomes among individual contributors. If significant results are found, practitioners using alternative software development methodologies or "tailored" Agile may want to consider adopting the practices examined in this study.

APPENDIX

Proposed Survey Items

Author(s)	Construct	Respondent	Scale	Item
Tripp et al. (2016)	**Burndown**	Developer	Likert (1-7)	Our team utilizes visual indicators (charts, graphs, etc.) of how well we are progressing DURING a work cycle.
				We use visual tools that allow team members to easily tell if the work is being completed on schedule.
				We plot our work completed against work planned on a chart.
	Ierative Delivery	Developer		At the beginning of each work cycle, the team and business owners agree on what will be delivered during the work cycle.
				The team gives input as to how much work can be completed in a work cycle.
				The team estimates the amount of work each feature will require to be completed.
				Our team lets business people make business decisions about releases, and technical people make technical decisions about releases.
	Stand-up	Developer		The team has a short meeting every day to discuss what is going on with the project
				Each day, all team members share with the team what they are working on.
				The team discusses issues together daily.
	Retrospective	Developer		On a regular basis, the team reflects on previous work and looks for ways to improve team performance
				At the end of each work cycle, the team asks itself "what went well" during the last work cycle.
				At the end of each work cycle, the team asks itself "what could be improved" during the next cycle.
Rich et al. (2010)	**Job engagement (Vigor)**	Developer	Likert (1-5)	I work with intensity on my job.
				I exert my full effort to my job.
				I devote a lot of energy to my job.
				I try my hardest to perform well on my job.
				I strive as hard as I can to complete my job.
				I exert a lot of energy on my job.
	Job engagement (Dedication)	Developer		I am enthusiastic about my job.
				I feel energetic about my job.
				I am interested in my job.
				I am proud of my job.
				I feel positive about my job.
	Job engagement (Absorption)	Developer		I am excited about my job.
				At work, my mind is focused on my job.
				At work, I pay a lot of attention to my job.
				At work, I concentrate on my job.
				At work, I focus a great deal of attention on my job.
				At work, I am absorbed in my job.
				At work, I devote a lot of attention to my job.
Lee and Allen (2002)	**OCB-I items (OCB's oriented towards individuals)**	Supervisor	Likert (1-7)	Help others who have been absent.
				Willingly give your time to help others who have work-related problems.
				Adjust your work schedule to accommodate other employees' requests for time off.
				Go out of the way to make newer employees feel welcome in the work group.
				Show genuine concern and courtesy toward coworkers, even under the most trying business or personal situations.
				Give up time to help others who have work or nonwork problems.
				Assist others with their duties.
				Share personal property with others to help there work.
	OCB-O items (OCB's oriented towards organizations)	Supervisor	Likert (1-7)	Attend functions that are not required but that help the organizational image.
				Keep up with developments in the organization.
				Defend the organization when other employees criticize it.
				Show pride when representing the organization in public.
				Offer ideas to improve the functioning of the organization.
				Express loyalty toward the organization.
				Take action to protect the organization from potential problems.
				Demonstrate concern about the image of the organization.
Williams and Anderson (1991)	**In Role Behaviors**	Supervisor		Adequately completes assigned duties.
				Fulfills responsibilities specified in job description.
				Performs tasks that are expected of him/her.
				Meets formal performance requirements of the job.
				Engages in activities that will directly affect his/her performance evaluation.
				Neglects aspects of the job he/she is obligated to perform. (R)
				Fails to perform essential duties. (R)

ABSTRACT

Employees believe that during the process of knowledge sharing, they may waste their time and resources. To protect their capital, investment, and power, employees believe hiding their knowledge from coworkers is one option that is available within the organization. This research focused on describing the experiences of why people do not share knowledge between their coworkers.

KEYWORDS: knowledge sharing, tie strength, communication, self-efficacy, attitude, trust

INTRODUCTION

Knowledge sharing is an organizational process defined as the knowledge provider sharing ideas, information, and suggestions based on personal experiences with a knowledge receiver (Rusly, Corner, & Sun, 2012; Teng & Song, 2011; Titi Amayah, 2013). Recently, scholars (Kane, Alavi, Labianca, & Borgatti, 2014) have defined the relationship between a knowledge provider and recipient as the provider controlling the recipient's ability to know and access the provided content while customizing the shared knowledge to the recipient's needs and situation (Ho & Ganesan, 2013).

Employees often assume that they may waste their time and/or resources during the knowledge-sharing process. To protect their intellectual capital and investment, and sustain power, employees often hide their knowledge from coworkers and view it as one behavioral option available within the organization (Connelly, Zweig, Webster, & Trougakos, 2012). However, knowledge sharing is highly important in today's business environment. The sharing and reuse of knowledge not only helps firms gain a competitive advantage but also increases the effectiveness of work (Gee-Woo, Zmud, Young-Gul, & Jae-Nam, 2005; Lee, Kim, & Kim, 2012). A firm's performance often relies on managers' skills and experience in using knowledge gained through knowledge sharing with colleagues rather than managers' individual or social skills (Kukenberger, Mathieu & Ruddy, 2015; Massingham, 2015).

A frequent concern of employees is the necessity of knowledge sharing with colleagues. Employees consider their knowledge part of their personal capital, investment, and power (Lam, Huang, & Chan, 2015). However, as prior research (Beck, Pahlke, & Seebach, 2014; Titi

Amayah, 2013) suggests, knowledge providers' motivations to share their knowledge are pressing factors that determine a person's motivation to contribute knowledge to others. Such motiviations include personal expectations of economic rewards, reputation benefits, normative considerations, and interpersonal and culture barriers and trust.

Many researchers have studied the motivational causes that explain knowledge sharing between providers and recipients. However, the lack of a theory-practice considering both providers and recipients represents a gap in the literature (Miao, Choe, & Song, 2011; Ragab & Arisha, 2013; Rusly et al., 2012) regarding the actual process of knowledge exchange. For example, how knowledge providers share knowledge may increase their reputation and lead to later reciprocal behavior (Connelly et al., 2012). It may also impact how staff behavior is affected by subjective norms (Bock, Zmud, Kim, & Lee, 2005).

A few employees feel that, the more knowledge is shared with their competitors, the greater the potential that threats to a provider's social capital, investment in time, and power will have future consequences. In addition, when knowledge providers can create or innovate new knowledge in knowledge management processes, they sometimes treat the processes as a strategic weapon in the organization (Heeseok & Byounggu, 2003). Consequently, knowledge providers and receivers can find themselves in a position that can deter or enhance the likelihood they will be laid off or promoted.

What are the actual experiences of sharing knowledge with colleagues? How and to what extent does motivation, strong/weak ties, organizational climate, organizational identification, and relationships potentially influence the sharing of knowledge among colleagues? The current research will be from the viewpoint of both knowledge providers and knowledge receivers where both are colleagues—in other words, coworkers and managers. This research focuses especially on motivational causes that explain knowledge sharing between providers and recipients. In addition, we posit that organizational learning factors impact an employee's knowledge-sharing intentions and constraints/opportunities.

What are the experiences of sharing knowledge with colleagues? How and to what extent does motivation, strong/weak ties, organizational climate, organizational identification, and relationships influence the sharing of knowledge among colleagues? The research will be from the viewpoint of both knowledge providers and knowledge receivers where both are colleagues—in other words, coworkers and managers.

LITERATURE REVIEW

Definition of knowledge

The knowledge-management literature can be roughly divided into two streams. The first stream regards knowledge as an asset capable of being stored, combined, and disseminated; the second is defined by the idea that knowledge is embedded in relationships and cannot be separated from actions (Nakano, Muniz Jr., & Dias Batista Jr., 2013). These streams distinguish between explicit and tacit knowledge. Explicit knowledge (EK) can be copied and stored in various formats, making it easy to transfer and share (Stevens, Millage, & Clark, 2010). Tacit knowledge (TK) develops incrementally based on personal experience and relies on personal judgment (Insch, McIntyre, & Dawley, 2008; McIver, Lengnick-Hall, Lengnick-Hall, & Ramachandran, 2013). Kane et al. (2014) defined the relationship between a knowledge provider and recipient as one where the provider controls the recipient's ability to know and access the provided content but must customize the shared knowledge to the recipient's needs and situation (Ho & Ganesan, 2013).

Knowledge-sharing intention

Knowledge sharing involves the exchange of both explicit and tacit knowledge relevant to the task, which includes communication, interaction, and the implicit coordination of the knowledge provider, who knows what to share with the receiver (Buvik & Tvedt, 2017). Knowledge sharing consists of the horizontal integration of dissimilar knowledge. That is, a comprehensive knowledge base delivers diverse knowledge interfaces among functional units and often includes reciprocal exchanges—including both providing and receiving knowledge—between staff members (Foss, Minbaeva, Pedersen, & Reinholt, 2009). This theme focuses on tacit knowledge at a personal level and proposes that knowledge providers can accept any challenge only if they feel comfortable that a knowledge or experience has been examined many times (Dingle, Stark, Cruwys, & Best, 2015). Only then are they willing to share that knowledge with recipients who could be motivated by group identification (Dingle et al., 2015). Gino, Argote, Miron-Spektor, and Todorova (2010) examined the effects of learning from different types of prior experiences (direct and indirect). They found that direct experience leads to higher levels of team creativity and product component divergence than indirect experience. Thus, prior experiences build a base for knowledge sharing across different areas (Cui & O'Connor, 2012).

Self-efficacy

Per social cognitive theory (SCT) (Bandura, 1986), there are two cognitive concepts: self-efficacy and outcome expectations. Both lead human behavior. This research defines self-efficacy as knowledge providers' perceptions of their own ability to share experiences and knowledge or the belief that they possess the skills and resources necessary for the recipient's success. Lin and Chen (2013) believe that self-efficacy defines employees' belief in their capability to learn effectively. George and Prybutok (2014) recognize that self-efficacy is an individual's belief in a person's ability to succeed in making important decisions. Salanova, Rodríguez-Sánchez, Schaufeli, and Cifre (2014) argue that self-efficacy beliefs clearly influence how people perceive both challenging tasks and the skills needed to successfully complete those tasks. The ideal situation to discuss this phenomenon is to have staff try tasks with which they feel comfortable given their knowledge, experience, and control rather than implementing tasks in a new area for them. (Ventura, Salanova, & Llorens, 2014).
In summary, whether organizations can successfully implement knowledge management is largely based on an organization's self-efficacy, how the executive level utilizes knowledge management, and the self-efficacy of the individual.

Tie strength

To maintain productive interpersonal relationships in an organization, employees need to trust each other and engage in frequent contact over a long period of time (Dahlander & McFarland, 2013; Uzzi, 1997). Over the past two decades, most social network researchers have focused more on the quality of personal relationships. If an individual believes the relationship is very important, involving more frequency, it is defined as a strong tie relationship. On the other hand, a weak tie relationship is less important, so the interaction is less frequent (Baker, Donthu, & Kumar, 2016). An area requiring more research is "intra-organizational task relationships and the factors leading to their formation and persistence" (Dahlander & McFarland, 2013).
Theory of Planned Behavior (TPB), Subjective Norms, and Attitude toward Sharing
"Subjective norms" are included as a direct determinant of behavioral intention in both the theory of reasoned action (TRA) (Fishbein & Ajzen, 1975) and the subsequent theory of planned behavior (TPB) (Ajzen, 1991). Such norms are defined as the perceived social pressure to

either perform or not perform a behavior and have received significant practical support as an important precursor to behavioral intention (Ajzen, 1991).
TPB states that three evaluation criteria—attitude (ATT), subjective norm (SN), and perceived behavioral control (PBC)—influence behavioral intention (BI), which, along with PBC, determines technology usage (use) (Ajzen, 1991). Intention is influenced by people's attitude toward a behavior, which is a function of their beliefs about the consequences of that behavior. This attitude, in turn, translates into either positive or negative feelings. Scholars (Marta, Pozzi, & Vignoles, 2014; Schwenk & Möser, 2009) have noted that an idea central to TPB is that it seeks to explain the relationship between an people's attitudes and behavior, and their behavioral intentions.
Recently, similar arguments have been made. Scholars believe that TPB "is the premise that a person's intention or stated plan is the most proximal predictor of behavior… [and that] intention is influenced by three sets of belief-based social cognitive constructs, namely, attitudes, subjective norms, and perceived behavior control (PBC)" (Hagger & Chatzisarantis, 2012, p. 198). Many empirical studies (Ajzen & Sheikh, 2013; Gissel, Thompson, & Pond, 2013; Levine & Strube, 2011; McPhee, Sears, & Wiesner, 2014; White, Thomas, Johnson, & Hyde, 2008) have indicated that attitudes, subjective norms, and PBC are all significantly and positively related to behavioral intentions.

Organizational communication

Collyer (2016) argued that face-to-face communication is a more effective way than X to eliminate the confusion. Recently, employees of all ages rely on new technology such as video/teleconference and social media tools (e.g., Twitter, Facebook, and Google Plus) to communicate in the organization. Especially, "Gen X and Gen Y business professionals are quite likely to consider that social networking tools will be the primary tools for team communication in the future" (Cardon & Marshall, 2015). Kodish (2017) emphasized that both communication and interaction provide the necessary background for building and sustaining trust.

Knowledge hiding

Employees who try to protect their competitive advantage in an organization have various ways to avoid directly answering the knowledge requester's question. The key to employees doing this effectively is that other employees cannot point to significant evidence to catch someone in the act. For example, those protecting their competitive advantage can just say, "Sorry, I just forgot," or, "This has been classified confidential, and I am not allow to share with you."
We define knowledge hiding as the knowledge provider withholding knowledge that has been intentionally requested by the knowledge recipient (Connelly et al., 2012). In addition, ČErne, Nerstad, Dysvik, and ŠKerlavaj (2014) believe intentionally hiding knowledge in a organization not only inhibits the creativity and productivity of other staff, but also increases the distrust between knowledge provider and receiver.

Trust

This research defines trust as a complex phenomenon that involves positive or confident expectations between knowledge providers and receivers based on a willingness to accept vulnerability and belief that the behavior between them is honest, sincere, and fair (Buvik & Tvedt, 2017; Ismail, 2016). At the organizational level, trust has been linked to staff satisfaction (Edwards & Cable, 2009), performance (Colquitt, Scott, & LePine, 2007), teamwork (Sargent &

Waters, 2004), leadership effectiveness (Gillespie & Mann, 2004), and negotiation success (Olekalns & Smith, 2007).
Trust in organizations involves the staff's willingness to be vulnerable to the entire organization's actions. This can enable cooperation and collaboration with the firm, which is examined in this research on inter-organizational knowledge sharing. This willingness exists only when an organizational climate clearly communicates its actions to staff through the environment. Thus, trust has become an important influence on knowledge sharing (Buvik & Tvedt, 2017), making it a key concept in this study on knowledge sharing.
There are three different types of trust: economy-based trust, information-based trust, and identification-based trust. All three must be established consecutively to reach to identification-based trust; then the identification-based trust positively affects knowledge-sharing intention (Hsu, Ju, Yen, & Chang, 2007; Ozlati, 2015).

Organizational learning

Empirical studies have found that organizational learning processes help to facilitate the development of IT innovations (Salaway, 1987), lower the knowledge barriers to the adoption and assimilation of innovations (Attewell, 1992; Fichman & Kemerer, 1997), overcome difficulties in implementing the innovations (Argyris, 1977), and enhance organizations' overall performance outcomes from innovating (Tippins & Sohi, 2003). Given this, the common empirical finding of improving organizational performance through learning from experience is argued to be effective only because greater organizational experience provides greater opportunity for organizational failure (Sitkin, 1992). However, existing evidence that failure is more important than success for organizational learning is entirely anecdotal (Cannon & Edmondson, 2001; Tax & Brown, 1998).
The bulk of prior organizational learning researchers have examined learning from aggregated organizational experience (Argote & Epple, 1990; Darr, Argote, & Epple, 1995; Ingram & Baum, 1997). Recent work, however, has begun to explore organizational learning from prior failure experience, disaggregated from total prior experience (Baum & Ingram, 1998; Haunschild & Sullivan, 2002; Miner, Kim, Holzinger, & Haunschild, 1999).

METHODS

Methodology

Our qualitative research was conducted utilizing grounded theory, as formulated by Glaser and Strauss (Glaser, 2017; Glaser, Strauss, & Strutze, 1968). Grounded theory is an integrative methodology. The approach is based on new theory being constructed from "past and present involvements and interactions with people, perspectives, and research practices" (Charmaz, 2006, p. 10). This research method helps the researcher uncover and understand the meaning of participants' lived experiences. It does so by applying an analytical process to derive theoretical understanding and uncover patterns and conceptual frameworks aimed at adding to the body of knowledge in both academic and practitioner communities (Patvardhan, Gioia, & Hamilton, 2015).

Sample

To understand the subjective experience of knowledge-sharing behavior, we conducted in-depth interviews with 29 interviewees who were selected from the researcher's personal social network. Interviewees included 20 people who work for a private company and nine students who are studying at local state university in California with at least three years of full-time job experiences. The average years of working experience was 20.6 years, and 35% of interviewees were female and 65% male.

Data collection

The interviews lasted 60 minutes on average. All interviews were digitally recorded with permission and were professionally transcribed. The interview protocol is shown in Appendix B. Most interviews were conducted face to face for the students who live in Sacramento County in order to guarantee interviewee privacy. If meeting face to face was impossible, the interviews were conducted over Skype.

Data analysis

Corbin and Strauss (2008) introduced an open-coding approach that included processes for selecting, categorizing, and labeling direct statements, such as first-order, informant-centric codes. Thus, this study implemented this concept for data analysis because it could be built to include more theoretical concepts, such as second-order, researcher-centric themes (Patvardhan et al., 2015). Finally, we could condense data analysis into more general theoretical concepts, such the overarching dimensions (Patvardhan et al., 2015). In the beginning, we coded by reviewing interview transcripts and identified all of the words that characterized basic ideas or concepts. Later, the next analyses implicated axial coding (Corbin & Strauss, 2008)—synthesizing and clustering the previous codes into higher-order themes. At this stage, we used constant comparative methods from Glaser and Strauss (1968) and compared data over time and across codes. Finally, this study applied grounded theory to convert the previously static and dimensions into a comprehensive diagrammatic summary. We used the qualitative data-analysis software NVivo to manage the transcripts and the data corpus, and we used constant comparative methods to compare and contrast data to establish the codes (Glaser, 1978). After uploading all the transcripts, we started reading through each transcript to understand content and to add memos on NVivo.

While working through key nodes of interest to us, we began to see differences in how interviewees talked about their knowledge-sharing experiences and stories. For now, we have coded these stories as tacit knowledge that may be potentially beneficial for their future careers. Figure 1 displays the ordering and structuring of the data that identify the codes, themes, and dimensions that capture the early (prologue) stages of the knowledge-sharing processes. We accumulated the informant-based, 121 first-order codes into 14 researcher-induced second-order themes, which we further distilled into seven overarching theoretical dimensions.

Figure 1. Prologue to the knowledge-sharing data structure

RESULTS

Many knowledge-sharing stories were reported during the interview processes, resulting in seven overarching theoretical dimensions that impacted knowledge-sharing behavior: self-efficacy, attitude, tie strength, organizational communication, trust, knowledge hiding, and organizational learning. Interviewees are referenced in both the Findings and Discussion sections.

Finding 1: Being an employee with a strong self-efficacy (13 of 29 interviewees' quotes support this finding)
This finding includes the knowledge providers who have a strong self-efficacy in their knowledge-sharing processes. Scholars define self-efficacy as individuals' beliefs regarding their own ability to both realize an action and to manage tasks and situations (Battisti, Gilardi, Siletti, and Solari, 2014; Mesurado, Richaud, & Mateo, 2015). Both knowledge provider and receiver believe they feel more confidence in the knowledge-sharing processes.

Example Quotes:
"When I trained people I felt like I trained them the best in a way. Because I was really candid about what they expect." (Interviewee 11)

"That was a positive to me to know that my manager trusted me enough to train someone new and expect that I would pass on that information to them." (Interviewee 15)

"…then we created a very excellent website to house all of those things so that the potential students, the potential future teachers, the potential people that would engage with this project could begin to believe that this was something that they wanted to be a part of." (Interviewee 21)

"But they could and would have had the confidence in me that we could have gotten that job done in 10 months. But because I think the cascading." (Interviewee 8)

"I feel very comfortable and happy at the same time because I knew I have more knowledge than she did." (Interviewee 1)

Finding 2: Being an employee with a positive attitude toward sharing knowledge (22 of 29 interviewees' quotes support this finding)
This finding includes the knowledge providers and/or receivers who have a positive attitude toward sharing their knowledge. TPB (Ajzen, 1991) suggests that the behavioral intention to perform a particular behavior is predicted by the attitude toward the behavior. This research defines that attitude toward performing the knowledge-sharing behavior from knowledge provider to receiver.
Example Quotes:

"She wanted to know who did it and she was not aware of that software, how to look it up, how to use it so I teach her how to use it and then she used it after that all the time." (Interviewee 2)

"She shared it to everybody and she explain it but she encourage everybody to go…"

"By sharing the information with my deputy chiefs, they were able to start project planning on a collaborative basis with our police unions and our supervisors." (Interviewee 3)

“He literally took out a pad and pencil a notepad and started taking notes.” (Interviewee 25)

“I've been a team player and it was my every intention to help the team and to position the team in the best light.” (Interviewee 6)

“My coworkers reach out to me I always have a very positive sharing my knowledge with my coworker and training them to give their experience on what I have been going through, it always is a very pleasure for my coworker.” (Interviewee 7)

“The biggest regret that you will have is not trying. You won't regret because you try it and you fail. You will regret because you never tried." So I said, "You might as well figure out how, I mean, do the math, see how much you need and do what you can to save.” (Interviewee 21)

Finding 3: Building a good relationship (13 of 29 interviewees’ quotes support this finding)
If the knowledge provider and receiver believe the relationship is very important, involving more frequency, it is defined as a strong-tie relationship between both the knowledge provider and receiver. From this study, the tie strength could be defined based on the frequency of interactions between both the knowledge provider and receiver (Hong, Pavlou, Wang, & Shi, 2016).
Example Quotes:
“If I feel like that person has a pretty close relationship with me, I would sit down with them.” (Interviewee 28)

“I'd say that the knowledge that he gave me was helping me understand how the university works. He would give me this knowledge in—we would have weekly one-on-one.” (Interviewee 3)

“When it comes to relationship—building in that environment—the better your relationship with your clients, of course, the better your project, or your outcomes or your sales, or whatever it is may be.” (Interviewee 27)

“And then there was a lot of background about the work environment in making them feel comfortable introducing them to co-workers. I think the positive out of that was kind of building a relationship with a new trainee.” (Interviewee 11)

“Thinking about it now it's probably a really positive experience because I was really sad that I couldn't spend my holidays with my own family but I spent it with my Marie Callender's family. I think despite all the turmoil and the frustrations of the holiday dealing with horrible customers, it brought everyone together. At the end of the day.” (Interviewee 10)

“We had a very candid honest one-on-one discussion. And help him to reflect and to be honest to himself.” (Interviewee 25)

Finding 4: Being a good communicator (26 of 29 interviewees’ quotes support this finding)
This study defines organizational communication as fundamental in working environments when associating between knowledge provider and receiver, and enabling organizations to achieve the knowledge-sharing processes (Musah, Zulkipli, & Ahmad, 2017). Organizational communication comprises how employees communicate multifaceted details—such as emails

(Cardon & Marshall, 2015), meetings, trainings, and appointments—in formal or informal situations (Stephens & Barrett, 2016).
Example Quotes:

“This is a good communication and the result of good communications and also the trust it established between us.” (Interviewee 24)

“The best important thing is the communication. If you have a good communication for everybody, you can quickly talk—reach to them and if there is a mistake you share with them. If there is an error, if there is a negative experience, you should reach them very quickly.” (Interviewee 29)

“I took that information, I not only shared it with my team or my deputy chiefs. I have two deputy chiefs of police. I shared that information with them in order to begin project planning.” (Interviewee 17)

“The way that he communicated to me was that I let the team down because I was not responsive to the request. He didn't seem to want to want to hear that there could have been a miscommunication, a misunderstanding, but clearly what was not at play was my commitment, my sincerity, or my integrity.” (Interviewee 8)

“It was miscommunication but I also think that it was a mischaracterization. With respect to my underline intentions, my underline commitment, or my underline diligence, I think that was mischaracterized and misperceived by my boss, and it left me feeling a bit alienated, mischaracterized, and misjudged because I felt he was making a judgment about my character rather than my actions.” (Interviewee 9)

“That, to me, was a great information share with my executives, because I knew how to talk to them with the way wanted to get information.” (Interviewee 18)

“If he wasn't very efficient at communicating precisely and clearly, then a lot of time would be wasted and so he had to explain a lot of information in a very short amount of time, to a lot of people. And so he had to develop that skill of communicating that way.” (Interviewee 10)

Finding 5: Being an employee that exhibits knowledge hiding behavior (12 of 29 interviewees’ quotes support this finding)
Scholars (Connelly et al., 2012) defined “knowledge hiding as an intentional attempt by an individual to withhold or conceal knowledge that has been requested by another person” (p. 65). ČErne et al. (2014) believe intentionally hiding knowledge in an organization not only inhibits the creativity and productivity of other staff, but also increases the distrust between knowledge provider and receiver.
Example Quotes:
“In a big company, you would see people hold information back, knowledge back because they wanted to deliver that information in a meeting. They wanted to be the one that looked the smartest or they wanted to be the one that everybody looked to or their knowledge would help them get a promotion.” (Interviewee 28)

“I had the feeling and impression that the person did not want to teach me how to do it.” (Interviewee 22)

“They didn't respond. They told him that it was just not okay, but they never explained to him why it was not okay or what the reason behind it was. They just said, "Employee, that's not okay.” (Interviewee 11)

“I felt like, that information had been hidden from me, had not been fully disclosed, had not been shared so as to forewarn me, so as to position me, and so as to educate me on the level of discontent, on the level of frustration and the level of lack of confidence in my leadership. I felt like there had not been full support, unity, and loyalty supporting my leadership. I felt let down.” (Interviewee 9)

“One negative experience with the peers is that it's more of a evil thing. If the person are the same level trying to provide any trainings or knowledge, they might feel that, ‘I know better than him,’ that is one negative experience with the peers. They don't try to… because they think, ‘I know better than this guy,’ or that kind of equal thing is one negative experience.” (Interviewee 2)

“So that, basically, the don't pay attention thinking that, ‘Oh, I know what this guy ... This guy is trying to provide training because he wants to prove his management, his doing some relational activities beyond his job to promote himself or to get a better reputation with his boss.’ That's how they feel, rather than trying to focus on what is in the training, or knowledge session.” (Interviewee 5)

“It's same across peers and colleagues. Same thing. Even if they are peers, same thing. Here it's more of a, because of the job security. Sometime people not tend to share the knowledge.” (Interviewee 7)

Finding 6: Building up trust in the organization (14 of 29 interviewees’ quotes support this finding)
Trust is the most important criterion between knowledge providers and recipients, and makes it more likely for knowledge sharing to occur through the knowledge transfer process (Gooderham, Minbaeva, & Pedersen, 2011). Trust is a feeling one person has regarding another person’s capability and reliability, as supported by that person’s past actions. From this study, we defined knowledge provider (the trustor) willingness to be vulnerable to knowledge receiver (the trustee) on the basis that the trustee will act according to the trustor’s confident expectations (Mayer, Davis, & Schoorman, 1995; Schoorman, Mayer, & Davis, 2007).
Example Quotes:
“This is a good communication and the result of good communications and also the trust it established between us.” (Interviewee 29)

“Some colleagues of you give you some wrong information. You as a receiver the first time you trust your colleague, because he's your friend because your colleague, he won't tell you wrong things.” (Interviewee 2)

“You should process anything that comes to your to your colleagues and to your friends. You know that's a trusted person, but before you share with other people, you should process that.” (Interviewee 3)

“I felt I could trust them, and I could rely on them and I knew that they would help me no matter what and I would do the same for them.” (Interviewee 4)

“I shared with him because I have trust in his leadership, in his intention, in his thoughtfulness.” (Interviewee 9)

“Because I have trust in the Chief's intentions and knowing his thoughtfulness towards building community.” (Interviewee 12)

“I trust each of you enough within our team that you should have some of this confidential information because I know you're not going to go out and spread it anywhere.” (Interviewee 18)

Finding 7: Building an organizational learning working climate (15 of 29 interviewees’ quotes support this finding)
Organizational learning involves not a simple sender-to-receiver transmission (Ingram 2002), but sophisticated processes mediated by environmental entities, such as populations, geographic regions, and the communities of interests. Organizational learning theorists have long held that organizations learn primarily through processes of “problematic search,” which they engage in only after experiencing failures (March & Shapira, 1992).
Example Quotes

“I had to teach my immediate manager because she was just new, she just got hired, how to use some software on the company.” (Interviewee 22)

“I shared to another new employee, I was training her and she came in and I showed her and I said, "Grab a piece of paper, make sure you write this down because you will forget about it.” (Interviewee 23)

“Sometimes where you have a colleague, and he doesn't know about the sensitivity of the issues and you share with him some issues that.” (Interviewee 24)

“I mentioned that the colleagues should be educated, should be informed, should be properly educated about the issue you wanted to mention.”(Interviewee 12)

“I took that information; I not only shared it with my team or my deputy chiefs. I have two deputy chiefs of police. I shared that information with them in order to begin project planning. But beyond that, Tony, I shared it with the City Police Chief to inform him of our intention and our progress towards gaining a grant to implement the body-worn camera.” (Interviewee 17)

“For that I interacted with my senior professor and my junior professor. We collaborate through online, asking questions, getting responses. Also I send that information to other people who are not in the meeting, going back and forth to come up with a finalized set of learning goals and objectives. Is that an example of collaboration?” (Interviewee 5)

“Normally I need give them by the difference task or different jobs, to give them the appropriative knowledge when I deliver to them.” (Interviewee 8)

CONCLUSIONS AND FUTURE DIRECTIONS

It appears that the pressure of managerial expectations associated with company policies and management reduces the intrinsic satisfaction of sharing knowledge with others. In the presence of highly subjective norms, the motivating influence of a favorable attitude toward

sharing knowledge is weakened throughout the organization. This section analyzes the factors that impact knowledge-sharing intention at both the personal and organizational level.

At the personal level, interviewees believe that building a strong relationship with other staff is a necessity for an organization because they can gain trust from each other. Based on the findings, this research emphasizes trust as the core component that influences all factors for sharing knowledge between the knowledge provider and receiver. Trust was tied to individual relationships, and it is the fundamental condition for the knowledge-sharing process (Nelson, 2017). During the knowledge-sharing process, effective communication always improves the sharing of knowledge, and trust is established between knowledge provider and receiver. Max Evans (2015) posits that building trust using communications is important for sharing tacit knowledge.

Previous scholars have mentioned that trust is a key factor affecting knowledge sharing between the personal and organizational level (Buvik & Tvedt, 2017). Staff in particular easily build up strong ties and trust when they all experience the same pressure from work during a busy holiday season. For example, they sacrifice the opportunity to stay with their families because of work. On the other hand, a miscommunication causing misperceptions is often a disaster during the knowledge-sharing process because it can cause misjudgments by an organization's decision-maker.

Both knowledge provider and receiver feel they have a pretty good relationship with one another. They like to start the knowledge-sharing process because they have first built up trust. Sometimes, if one person is closed to another person, they would move to having lunch or a beer to have straightforward communication in an informal situation. Based on his own experiences, one interviewee believes that informal knowledge sharing has more efficiency than formal knowledge sharing. Kodish (2017) also believes that trust is the key component of the organizational process that jointly with communication channels to the environment. Further, both misunderstandings and miscommunication can cause a trust issue that leaves both knowledge provider and receiver feeling frustrated (Ferguson & Peterson, 2015).

Attitude is also an important subject influencing knowledge-sharing intention. Employees who have the appropriate attitude toward subjective norms always have good motivation to share their knowledge with others. Bandura (1997) defined attitude as a person's general beliefs that a target behavior will result in certain desirable outcomes that are conceptually similar to outcome expectancies. TPB is an extension of the theory of reasoned action (TRA) (Ajzen, 1991), which assumes that most human social behavior is under volitional control and therefore can be predicted from intentions alone.

TPB states that three evaluation criteria—attitude (ATT), subjective norm (SN), and perceived behavioral control (PBC)—influence behavioral intention (BI), which, along with PBC, determine technology usage (use) (Ajzen, 1991). Intention is influenced by people's attitude toward a behavior, which is a function of their beliefs about the consequences of that behavior. This attitude, in turn, translates into either positive or negative feelings. Scholars (Marta, Pozzi, & Vignoles, 2014; Schwenk & Möser, 2009) have noted that a central idea of TPB is that it seeks to explain the relationship between an individual's attitudes and behavior and their behavioral intentions.

From our findings, a knowledge provider with positive attitude always toward to share their knowledge to receiver, and a receiver always with a positive attitude toward to obtain a knowledge from providing. If an employee does not want to say anything against other employees, an inappropriate attitude always impacts the knowledge sharing with a negative intention among employees and frustrates the whole organization. Not only does this neglect and underestimate the cohesive power of the entire organization, but also the inappropriate attitude damages the trust between employees and breaks their ties. Per TPB, all of the attitudes toward sharing or toward learning to influence behavior intention.

Both knowledge provider and receiver gain self-confidence during the knowledge-sharing process. For example, one of the knowledge providers in the study felt he had trained the receivers to the best of his ability, and he believed he was candid about what the receivers expected. A self-efficacy was built in his mind after the knowledge-sharing process. Kauppila and Tempelaar (2016) emphasized that self-efficacy (GSE) is the most important psychological trait that reinforces individuals' behavior. Per our findings, knowledge providers' beliefs in their capability influence both the organizational expectations they set for themselves and their obligation to challenges during the knowledge-sharing processes. Bandura (2015) associated both social cognitive theory and goal theory, and that has been confirmed by our findings—the higher individual self-efficacy, the higher the goals people set for themselves.

Because knowledge receivers provided the knowledge provider with feedback that the knowledge was communicated relatively well, good communication was necessary. Another interesting phenomenon from the knowledge provider is that she felt very comfortable and happy after the knowledge-sharing process because she knew she had more knowledge than the receiver.

Knowledge hiding was the only factor that negatively impacted knowledge-sharing behavior in this study. The knowledge receivers felt that the knowledge provider did not want to share information with them and refused to explain the reasons; it is difficult to speculate on the reasons behind this behavior from the knowledge provider. Knowledge hiding behavior not only breaks the strength of ties but also destroys trust, causing the knowledge provider to be unwilling to share anything more with the receiver (ČErne et al., 2014). One of the interviewees who worked at a software company for many years emphasized that knowledge hiding is a very common behavior in the information technology field. Staff used to share knowledge in front of the manager to make a favorable impression. The reason for this behavior is that staff may have a psychological safety issue, such as worrying about being replaced in the organization.

Organizational learning is the only environmental factor that impacts the knowledge-sharing intention. Many of the interviewees believe it is a manager's responsibility to create a policy that rewards knowledge-sharing behavior and to build up an organizational learning environment to encourage staff to share knowledge with each other to improve the performance of the entire firm.

This study has several limitations that should be addressed in future research. First, this research did not go in-depth into the possible influences of managerial solutions to resolving knowledge-sharing issues. For example, an inappropriate attitude and lack of communication both cause a barrier to knowledge sharing in the organizational climate. In addition, one of the interviewees believes technology is not a necessary tool for improving the knowledge-sharing process. For example, staff like to use telecommunication in their training courses, which has created many issues, such as poor signals or background noise between the knowledge provider and receivers. Secondly, our samples included the U.S.A. and an Asian country, so this study represents responses based on Eastern and Western cultural behavior. For example, comparing a few Asian samples and American samples, such as a family business from each culture, may make our findings more culture-specific. This study did not closely analyze diversity. Although the operational and managerial practices may be similar to other countries, "Chinese culture has the tradition of viewing one's politeness in social interactions as a virtue" (Wang, Liu, Liao, Gong, Kammeyer-Mueller, & Shi, 2013, p. 1001). Thus, more multi-cultural and ethnic environmental samples may make this study more interesting in future research.

This research study proposes that organizations must recognize when members embody feelings of knowledge-sharing behavior that could potentially increase the firm's overall competitive advantage. It is recognized that it is difficult to create adequate rewards to encourage knowledge providers. Given this, it is a challenge for the management level to consider how to reduce these negative feelings for knowledge providers and to encourage the

mutual social exchange relationships that are important for driving a knowledge-sharing organizational climate. Considering that inter-organizational knowledge sharing is an issue that has inspired a great deal of research, its benefits to knowledge providers have not been explored well.

Knowledge hiding is another challenge the management level must resolve, and this issue is more difficult to deal with because it is a feeling that knowledge receivers have but lacks significant evidence to prove. Knowledge hiding has overall impacts, such as ethics and performance issues, which affect the firm. Since trust is a core component that can be defined as a personal factor, it is included with other personal factors, such as tie strength, self-efficacy, attitudes toward sharing knowledge, communication, knowledge hiding, and impacts on knowledge-sharing intention. In addition, trust also influences environmental factors, such as organizational learning, which impacts knowledge-sharing intention.

This study provides a useful theoretical framework for understanding how trust interacts between the SCT, TPB, social networking theory (SNT), and organizational learning theories. Specifically, "the SCT suggests that the effects of personal attitudes (including optimism) are often determined by their interaction with important behavioral and environmental factors" (Hmieleski & Baron, 2009, p. 473). Based on SCT, this research offers a framework grounded in TPB to discuss the intention of organizational learning within a given enterprise.

There are theoretical and empirical gaps between TPB and SNT, and knowledge hiding/hoarding with SNT because literature seldom addresses this phenomenon. Attitude toward sharing is one of the important concepts from TPB, and we assume that a better and/or closer relationship exists between knowledge provider and receiver, which influences the knowledge provider's attitude toward sharing his/her knowledge with the receiver. We also assume that a stronger relationship exists between knowledge provider and receiver, which influences the knowledge provider's attitude toward hiding and hoarding his/her knowledge from the receiver. We expect that future empirical research can explore these areas.

The issue of evaluation is likely to play an important role, but because this study focused on organizational support for individual knowledge sharing, further elaboration and refinement are needed. Further research needs to substantiate the practical evaluation models and effective review processes to connect individual knowledge sharing to the knowledge process at the firm level. Next, it should tie team knowledge to firm performance. In addition, the results of this study led to the belief that service providers, customers, and/or vendors could be both knowledge providers and recipients. It would be interesting to know whether all three play this role and how this influences their firms' overall performance.

Because Bandura's SCT is based on a collaborative relationship between environmental, personal, and individual behaviors, it provides a useful theoretical framework for the understanding of the self-regulatory processes and self-efficacy concepts, and can be applied in many areas. Specifically, SCT suggests that the effects of a personal disposition (including optimism) are often determined by their interaction with important behavioral and environmental factors (Wood & Bandura, 1989). In our seven overarching theoretical dimensions, we can define organizational learning as an environmental factor, and self-efficacy, attitude toward sharing, tie strength, organizational communication, knowledge hiding, and trust as individual factors to examine the interaction to behavior intention. This future research can evaluate whether our findings can apply to both social cognitive theory and goal theory.

Another interesting topic for future research would be to examine how expertise (i.e., personal reputation) is highly valued in an organization, while mentoring or assisting others is not. In this case, do knowledge-sharing providers still have a high motivation to share their knowledge?

APPENDIX

Interview protocol

Introduction (interviewer): "Hello my name is Tony Tung. I am a doctoral student at Case Western Reserve University. Thank you so much for taking the time to meet with me today. I really appreciate it. Before getting started, there are a couple of things I would like to cover."

Purpose and Format for the Interview (Interviewer): "As a current student in the Case Western Reserve University Doctorate of Management (DM) program, I am interested in developing a greater understanding of the influence of intra-organizational staff attitudes toward sharing knowledge with their colleagues as both providers and recipients. I will ask you a series of open-ended questions on this topic, and I will also ask one or more follow-up questions as you respond. The interview will last approximately 60 minutes."

Confidentiality (Interviewer): "Everything you share in this interview will be kept in strictest confidence, and your comments will be transcribed anonymously – omitting our names, anyone else you refer to in this interview, as well as the name of your current organization and/or past organizations. Your interview responses will be included with all the other interviews I conduct."

Audio Taping (Interviewer): "To help me capture your responses accurately and without being overly distracting by taking notes, I would like to record our conversation with your permission. Again, your responses will be kept confidential. If at any time, you are uncomfortable with this interview, please let me know and I will turn the recorder off."

"Any questions before we begin?

The background: Knowledge sharing is an organizational process defined as the knowledge provider sharing ideas, information, and suggestions from his or her own experiences with a knowledge receiver.

1. Tell me about yourself and your career.

- Education - Highest Degree
- Family
- Job History and Current position, organization and culture
- The years of experience since you began working in California State?
- Anyone else influence your choice?

2: Please tell me about a time when you had a positive experience sharing knowledge to a peer.

- Describe the experience
- How important was the knowledge
- Describes Challenges
- Describes Successes
- Describe Frustrations
- Describe the positives
- Describes the negatives

3: Please tell me about a time when you had a negative experience sharing knowledge to a peer.

- Describe the experience
- How important was the knowledge
- Describes Challenges
- Describes Successes
- Describe Frustrations
- Describe the positives
- Describes the negatives

4: Please tell me about a time when you had a positive experience receiving knowledge from a peer.

- Describe the experience
- How important was the knowledge
- Describes Challenges
- Describes Successes
- Describe Frustrations
- Describe the positives
- Describes the negatives
- Etc…

5: Please tell me about a time when you had a negative experience receiving knowledge from a peer.

- Describe the experience
- How important was the knowledge
- Describes Challenges
- Describes Successes
- Describe Frustrations
- Describe the positives
- Describes the negatives

Conclusion

“Thank you so much for our conversation! I've had an enjoyable time and I hope you have as well. This has been extremely helpful. We have covered a lot of ground, but if by any chance I have missed anything, would it be OK to contact you again for a brief clarification on any particular points, if necessary?

One last thing - Is there anything else that we haven't discussed that you would like to add before we finish?

ABSTRACT

The relevance and demand for humanitarian operations is increasing every year, as evidenced by highly erratic climatic patterns and frequent natural disasters such as landslides, earthquakes, droughts, floods, and hurricanes. In this paper, we discuss the case of "Ockhi", a Category 3 tropical cyclone that hit the Indian Subcontinent in late 2017. The magnitude, spontaneity, and, severity of such events, which are referred to as *force majeure*, puts enormous pressure on humanitarian organizations and supply chains globally, which are often constrained with limited resources, but entrusted with multiple functions, including but not limited to roles of information dissemination, evacuation of people, search & rescue, coordination & control, agile deployment, mobilization of forces, logistics, salvage, recovery, and reconstruction. This paper is a pilot work, employing case study method that explores issues in Early Humanitarian Operations during high uncertainty scenarios in islands and coastal regions. The research findings reveal critical issues in: (1) Effective Synchronization between information systems and field operations, (2) Responsiveness due to access cut-off (black out) between command center in mainland and islands or remotely located coastal regions hindering supply chain agility during early phase of humanitarian operations, and (3) Flexibility of Operations due to inadequate preparedness, safe and robust cross-docking facilities, and shelters to endure peaks of cyclonic flooding conditions during the disaster at island territories. The data has been triangulated with two other cyclonic flooding disasters in 2018 for validation. The results and key takeaways are summarized; limitations and directions for future research are discussed.

KEYWORDS: Humanitarian Supply Chains, Early Phase Disaster Management, Information - Operations Synchronization, Supply Chain Agility, Cross Docking, Case Study Research

INTRODUCTION

The World Disasters Report (Sanderson & Sharma, 2016) issued by the International Federation of Red Cross and Red Crescent Societies, is dotted with grave calamities since the turn of the new millennium; the South Asian Tsunami (2004), Hurricane Katrina and Rita (2005), Sichuan Earthquake in China (2008), the Ebola Outbreak in West Africa (2014) and multiple cyclones of very-high severity in the Indian Ocean, to name a few. Around the world, over 6000 disasters were reported in the last decade, with 771911 people killed, 1.9 billion people affected, and US $ 1.4 trillion (2015 prices) of estimated damages. The frequency, scale and severity of these catastrophes, which are referred to as *force majeure*, or 'Acts of God', puts enormous pressure on humanitarian operations and supply chains globally, which are often constrained

with limited resources, but entrusted with multiple functions, including but not limited to the roles of information dissemination, evacuation of people, search & rescue, coordination & control, agile deployment & mobilization of forces, logistics, salvage, recovery, and reconstruction. According to data from Centre for Research on the Epidemiology of Disasters (CRED), there has been a sharp spike in the frequency of floods and cyclones since the mid-1990s (Peduzzi, 2005) with significant impact on human lives, particularly for people living in low and middle income countries, and endangering the existence of island nations and coastal states. Table 1 shows the Top 10 countries in the world with the highest human impact due to natural disasters in the year 2016. It is evident that highest number of the deaths in absolute numbers, and per 100,000 inhabitants are in countries that are coastal states or islands, while 4 of the top 5 countries that were affected (on per capita basis) are island nations. More recent data from CRED (2017) also paints a similar picture, but the economic costs were much higher during recent disaster events particularly related to cyclonic storms and floods. In 2017 alone, 84.6% of the damage due to natural disasters was accounted by storms (cyclones, hurricanes or typhoons as they are referred to in different geographies). While hurricanes Harvey, Irma and Maria caused significant economic loss and damage in the Americas, particularly in the Caribbean region, India witnessed the highest number of deaths due to natural disasters in 2017 with 2,300 casualties and over 22 million affected inhabitants. Tropical Cyclone Ockhi, the case-in-context of this paper, inimitably stands out as one the most catastrophic of cyclonic disasters that hit the Indian subcontinent in the last decade, particularly affecting island territories, both in terms of human casualties and economic damage.

Tropical Cyclone Ockhi was a first in over 40 years to have travelled over 2000 kilometers around the west coast of peninsular India, starting as a depression in south-west Bay of Bengal on 29th November 2017, and moving up along the west coast where it finally dissipated off the coast of Gujarat on 6th December 2017, wreaking havoc and destruction along the way in Sri Lanka, Maldives, Lakshadweep Islands, and the southern states of India. It was impromptu, and held out as an aberration in the Disaster Response efforts which had seen continual improvement in the last decade, in terms of casualty prevention through early action; critical to this being early warning systems, rapid information dissemination and agile deployment and early evacuation in disaster prone areas.

Table 1 – Top 10 countries in the world with the highest human impact due to natural disasters in 2016

Deaths (number)		Deaths per 10^5 people		Affected (in millions)		Affected per 100,000 people	
China	1,151	Haiti	5.56	India	331.2	Micronesia	96,113
India	884	Fiji	5.16	China	13.0	Haiti	54,076
Ecuador	686	Ecuador	4.25	Ethiopia	10.2	Somalia	43,571
DPR Korea	598	DPR Korea	2.39	Malawi	6.5	Fiji	39,792
Haiti	596	Macedonia	1.06	Haiti	5.8	Marshall Islands	39,628
Pakistan	310	Rwanda	1.00	Somalia	4.7	Malawi	37,759
Italy	299	Sri Lanka	0.97	Zimbabwe	4.1	Mongolia	32,611
Indonesia	251	Taiwan	0.90	S. Sudan	3.6	S. Sudan	29,352
USA	250	Nepal	0.63	Vietnam	3.6	Swaziland	27,196
Taiwan	212	Italy	0.49	Bangladesh	3.2	Zimbabwe	26,277

LITERATURE REVIEW

Humanitarian logistics and supply chain research is still an emerging and continually evolving field of study. It is still being defined, mapped in literature, and contextualized to reflect realities and specific phenomena on ground. Since 2005, there has been a spike in research on humanitarian operations, logistics and supply chains. Researchers including Gupta et al. (2016), Kunz et al. (2017), Starr & Wassenhove (2016), Van Wassenhove (2006), Kovács & Spens (2007) have outlined the major gaps, broad directions and challenges for research in humanitarian logistics. In the last decade, there have been several pioneering efforts in this field, including case studies on organizational partnerships (Tomasini & Wassenhove, 2009), analysis of trends, developments and unique features of humanitarian logistics (Holguín-Veras et al., 2012; Kovács & Spens, 2011), application of Operations Research techniques for humanitarian logistics (Özdamar & Ertem, 2015; Wassenhove & Martinez, 2012), solutions to fleet management issues (Martinez et al., 2011) and problems related to vehicle procurement policies (Eftekhar et al., 2014). However, much of the research work is scattered and isolated in silos with few interlinkages; and to the best of our knowledge there is little grounded, empirical or case based research on recent developments in early phase of humanitarian operations with a focus on supply chain agility. The literature on early humanitarian operations is even scarcer in the Asian context, particularly from the Indian subcontinent that has been severely affected by cyclonic events from time to time. This is profound considering the number, frequency and intensity of cyclones that hit the North Indian Ocean region (refer Table 2) in the last decade, especial the coastal belts of peninsular India. The list represented in Table 2, was compiled by the authors from secondary sources, and comprises of cyclonic storms in the period from 2007-2018, with sustained 3-min. winds having speed greater than 65 km/h. The list includes severe cyclones, and those that would fall in the 1-5 Category Hurricanes, according to the classification by the National Hurricane Centre (NHC). Tropical depressions and deep depression systems were excluded from this list as they weren't disasters by themselves. Only when depressions picked up water vapor beyond a threshold value, gained strength, wind speed and intensity, would they become disastrous, meriting inclusion in the list that has been compiled. However, it may be noted that, for meteorologists and weather forecasters, deep depressions are important considerations in their "watch-list", as they could become potential tropical cyclones or hurricanes of higher intensity. It may observed from Table 2 that in the last decade , there was one Super Cyclone (Category 5) 'Gonu' in 2007, 9 extremely severe cyclones (Hurricane Category 3-4), 6 very severe cyclones (Category 2-3), 5 severe cyclones (Category 1), and 21 cyclonic storms (tropical storms as referred to by NHC) in the Indian Ocean. In this paper, the case-in-focus is Very Severe Cyclonic Storm "Ockhi" that hit the subcontinent in Nov 29 – Dec 6, 2017. The name, Ockhi, meaning "eye" in Bengali, was suggested by Bangladesh. Ockhi was a Category 3 major Hurricane that caused over US $ 5 billion of estimated damages, with fatalities numbering 245 deaths and 661 missing people.

The focus of this paper is Supply Chain Agility in Early Humanitarian Operations in Islands and Coastal regions. It is an underrepresented area in literature with very little done on research humanitarian operations in general, and supply chain agility of early operations related to disaster preparedness in particular. Although there have been studies on supply chain agility in commercial context (Gligor et al., 2015; Fayezi et al., 2017; Braunscheidel & Suresh, 2009; Swafford et al., 2008; Liu et al., 2013), there is little research on supply chain agility with focus on disaster preparedness, early action and information systems – field operations integration for early phase of humanitarian operations in island territories, which forms the basis of our first research question.

Table 2 – Cyclones in North Indian Ocean Region from 2007- 2018

Year	Name	Dates Active	IMD Category	Wind Speed	Areas Affected	Damage (USD)	Deaths
2018	Sagar	May 16 – 20	Cyclonic storm	85 km/h	Yemen, Somalia, Eritrea, Djibouti, Ethiopia	$80 million	52
2018	Mekunu	May 21 – 27	Ext. Sev. Cyclone	175 km/h	Yemen, Oman, Saudi Arabia	Unknown	11
2017	Maarutha	Apr 15 – 17	Cyclonic storm	75 km/h	Myanmar, Andaman and Nicobar Islands, Thailand, Yunnan	$23.4 thousand	4
2017	Mora	May 28 – 31	Severe Cyclone	110 km/h	Sri Lanka, India, Bangladesh, Myanmar, Bhutan, Tibet	**$1.36 billion**	135
2017	Ockhi	Nov 29 – Dec 6	Very Sev. Cyclone	155 km/h	Sri Lanka, India, Maldives	**> $5.07 billion**	245
2016	Roanu	May 17 – 22	Cyclonic storm	85 km/h	Sri Lanka, East coast of India, Bangladesh, Myanmar, Yunnan	**$2 billion**	227
2016	Kyant	Oct 21 – 27	Cyclonic storm	75 km/h	Andaman Islands, Myanmar, South India	None	None
2016	Nada	Nov 29 – Dec 2	Cyclonic storm	75 km/h	Sri Lanka, South India	$16 million	12
2016	Vardah	Dec 6 – 13	Very Sev. Cyclone	130 km/h	Sumatra, Andaman and Nicobar Islands, Thailand, Malaysia, Sri Lanka, South India	**$5.87 billion**	38
2015	Ashobaa	June 7 – 12	Cyclonic storm	85 km/h	Oman, United Arab Emirates	Minimal	None
2015	Komen	July 26 – Aug 2	Cyclonic storm	75 km/h	Bangladesh, Myanmar, Northeastern India	$21.1 million	170
2015	Chapala	Oct 28 – Nov 4	Ext. Sev. Cyclone	215 km/h	Oman, Somalia, Yemen	Unknown	9
2015	Megh	Nov 5 – 10	Ext. Sev. Cyclone	175 km/h	Oman, Somalia, Yemen	Unknown	18
2014	Nanauk	Jun 10 – 14	Cyclonic storm	85 km/h	Pakistan, Oman	None	None
2014	Hudhud	Oct 7 – 14	Ext. Sev. Cyclone	185 km/h	Andaman and Nicobar Islands, India, Nepal	**$3.4 billion**	124
2014	Nilofar	Oct 25 – 31	Ext. Sev. Cyclone	205 km/h	India, Pakistan	Minor	None
2013	Viyaru	May 10 – 17	Cyclonic Storm	85 km/h	Indonesia, Thailand, Sri Lanka, India, Bangladesh, Myanmar	>$5.14 million	107
2013	Helen	Nov 19 – 23	Severe Cyclone	100 km/h	India	$800 million	11
2013	Lehar	Nov 23 – 28	Very Sev. Cyclone	140 km/h	Malay Peninsula, Andaman and Nicobar Islands, India	None	None
2013	Madi	Dec 6 – 13	Very Sev. Cyclone	120 km/h	Sri Lanka, India, Maldives	Unknown	None
2013	Phailin	Oct 8 – 14	Ext. Sev. Cyclone	215 km/h	Malay Peninsula, Andaman and Nicobar Islands, India, Myanmar, Nepal	>$658 million	45
2012	Murjan	Oct 22 – 26	Cyclonic storm	75 km/h	Yemen, Somalia	Minimal	None
2012	Nilam	Oct 28 – Nov 1	Cyclonic storm	85 km/h	Sri Lanka, India	56.7 million	75
2011	Keila	Oct 29 – Nov 4	Cyclonic Storm	65 km/h	Oman, Yemen		14
2011	Thane	Dec 25 – 31	Very Sev. Cyclone	140 km/h	India	235 – 275 million	46
2010	Bandu	May 19 – 23	Cyclonic Storm	75 km/h	Somalia, Yemen		1
2010	Laila	May 17 – 21	Severe Cyclone	100 km/h	India	118 million	65
2010	Phet	May 30 – Jun 7	Very Sev. Cyclone	155 km/h	Oman, Pakistan, India	780 million	44
2010	Giri	Oct 20–23	Ext. Sev. Cyclone	195 km/h	Bangladesh, Myanmar, Thailand, Yunnan	$359 million	157
2010	Jal	Nov 1 – 8	Severe Cyclone	110 km/h	Thailand, Malaysia, India	392 million	117
2009	Bijli	Apr 14 – 17	Cyclonic Storm	75 km/h	Eastern India, Bangladesh, Myanmar		3
2009	Phyan	Nov 9 – 12	Cyclonic Storm	85 km/h	India	$64.9 million	28
2009	Ward	Dec 10 – 16	Cyclonic Storm	85 km/h	Sri Lanka, India		
2009	Aila	May 23 – 26	Severe Cyclone	110 km/h	India, Bangladesh	$553 million	330
2008	Rashmi	Oct 25 – 27	Cyclonic Storm	85 km/h	India, Bangladesh	Unknown	28
2008	Khai Muk	Nov 13–16	Cyclonic Storm	65 km/h	India (Andhra Pradesh)	$314 million	0
2008	Nisha	Nov 25–29	Cyclonic Storm	85 km/h	Sri Lanka, India (Tamil Nadu)	$594 million	204
2008	Nargis	Apr 27 – May 3	Ext. Sev. Cyclone	165 km/h	Andaman and Nicobar Islands, Bangladesh, Myanmar, Thailand, Laos, Yunnan	**$12.9 billion**	138,366
2007	Akash	May 13 – 15	Cyclonic Storm	85 km/h	Bangladesh, Myanmar, India	$982 million	14
2007	Yemyin	June 21 – 26	Cyclonic Storm	65 km/h	India, Pakistan, Afghanistan	**$2.1 billion**	983
2007	Sidr	Nov 11 – 16	Ext. Sev. Cyclone	215 km/h	Bangladesh, West Bengal, Northeast India	**$2.21 billion**	~15,000
2007	Gonu	Jun 1 – 7	Super Cyclone	235 km/h	Oman, Iran	**$4.4 billion**	78

Source: Compiled by the authors

This gap is supported by recent research on disaster preparedness (Oloruntoba et al., 2018) wherein the case for further empirical case studies has been made, considering the needs of disaster preparedness in specific contexts, relationships and partnerships between stakeholders for synchronization of information systems and ground operations of early humanitarian operations. Based on the above gap, we formulate our first hypothesis:

H1: *The level of integration between Disaster Information Systems & Field Operations mediates relationship between Resource Capacity and Effectiveness of Early Humanitarian operations.*

Hypothesis 1 follows from the gap in understanding relationship between resource integration between multiple stakeholders involved in early humanitarian operations.

Disaster Information Systems are operated by multiple agencies including National Meteorological Department, Military Meteorological Agency and other private organizations. Authentication of reliable information and deployment of field forces is a critical link in effectiveness of Early Humanitarian operations. Field forces carrying out the operations, such as National Disaster Relief Force, Navy and the State Police, often operate under different structural hierarchies, affecting the level of resource integration between participating agencies (Fawcett & Magnan, 2002). This makes supply chain integration more of rhetoric than reality. The first research question explores the relationship between resource integration and effectiveness (a dimension of supply chain agility) of early humanitarian operations.

Charles et al. (2010) in their pioneering work on defining and measuring supply chain agility formulated agility – maturity framework for supply chains. They demonstrated the use of this framework for the case of Yogyakarta earthquake that hit Indonesia in 2006. However, this case, like most other illustrations of supply chain agility in extent literature, is on post-disaster relief, including reports from the US Navy (McCall, 2006; Byman et al., 2000; Margesson, 2005; Siegel, 1990) on Humanitarian Aid in Pacific region. We observe lacunae in research on agility of humanitarian supply chains for pre-disaster and early phase of humanitarian operations in general, and those concerning island territories in particular. This needs a specific focus as early humanitarian operations in island territories come with a different set of challenges. The time pressures notwithstanding, during cyclonic disasters, island territories are usually cut off from mainland command centers making access, communications, information coordination, logistics and last mile connectivity (Balcik et al., 2008; Kovács & Spens, 2007; Stapleton et al., 2009) extremely difficult or near impossible. According to the classification of disasters and operational complexity by Apte et al. (2015), Cyclonic Storms in Island Territories would fall in the Fourth Quadrant (refer Figure 1), the most extreme of conditions. This makes humanitarian operations in island territories the most difficult to manage according to this classification as the locations are dispersed and the onset of time is sudden.

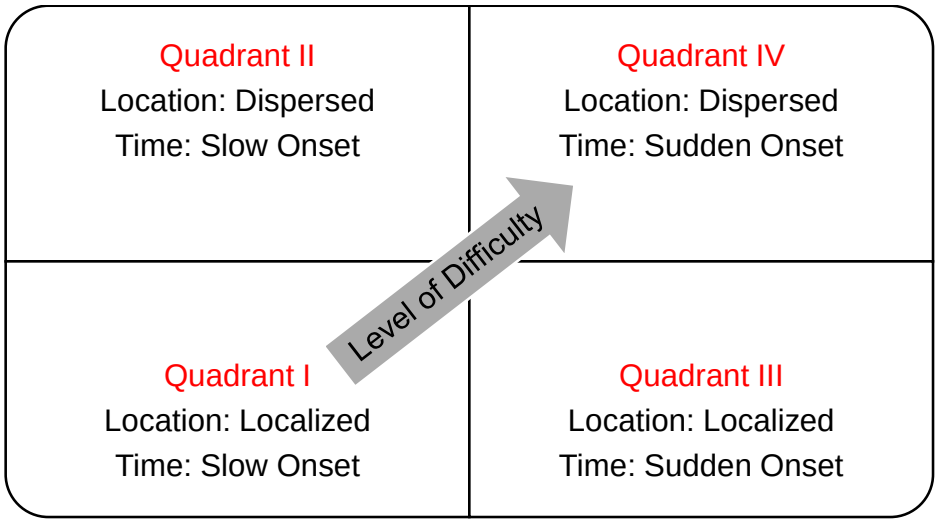

Figure 1 - Classification of Disasters and Operational Complexity (adapted from Apte et al., 2015)

Furthermore, early humanitarian operations particularly the evacuations, search and rescue operations warrant high levels of responsiveness (another dimension of supply chain agility), requiring the operations to be performed in a few hours (refer Figure 2 for Phases of Humanitarian Operations) to be successful. From Figure 2, it may be noted that the agility warranted during assessment and deployment phases are critical as these activities during these stages, which include, authentication and issue of warnings, preemptive evacuations, search & rescue, activating cross-docking facilities and pre-stocked inventories need to be carried out in a period of few hours or 1-2 days. It follows from this that agility of early humanitarian operations in island territories and remote or isolated coastal regions can become the deciding factor between the number of lives saved *versus* human casualties. This is because access and supplies to island territories are cut-off during the blackout phase when the cyclonic disaster strikes, usually at peak magnitudes.

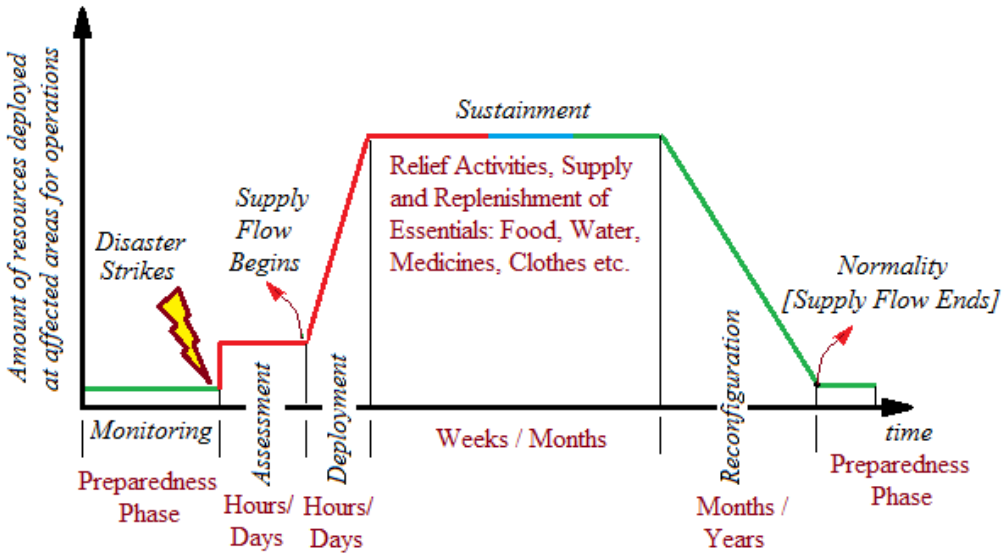

Figure 2 - Phases of Humanitarian Operations

Source: Modified from Balcik & Beamon (2008) and Charles et al. (2010)

It therefore follows, in light of the above, that the responsiveness (Kim, 2014) dimension of agility for humanitarian supply chains at nodal points in dispersed island clusters gains prominence due to the peculiar nature of island territories. Whether standalone supply chain capabilities at nodal points in island clusters (without leveraging mainland supply chain networks during early phase) affects the responsiveness of early phase of humanitarian operations, forms the basis of our second research question. The ability to evaluate, quickly respond and cover needs (captured by variable - *velocity*) in isolated island clusters and coastal zones without external help, which often comes with a time lag, is the focus area for our second hypothesis, which is thus formulated:

H2: *Standalone Nodal Resource Characteristics (size, type of fleet units for logistics, and training of stationed field forces) in Island Territories moderates the relationship between Velocity and Responsiveness of Early Humanitarian Operations.*

In the Blackett Memorial Lecture (Van Wassenhove, 2006), Humanitarian Logistics is described as Supply Chain Management in "High Gear". The efficiency, agility (inclusive of the three dimensions, namely effectiveness, responsiveness and flexibility) and resilience demanded from humanitarian operations make the nature of such operations crème-de-la-crème of all supply chain activities. Supply chains with high level of maturity, are necessarily built in with product-volume-delivery-mix flexibilities (Charles et al., 2010), in addition loading thresholds on the dimensions of responsiveness and effectiveness (refer Figure 3).

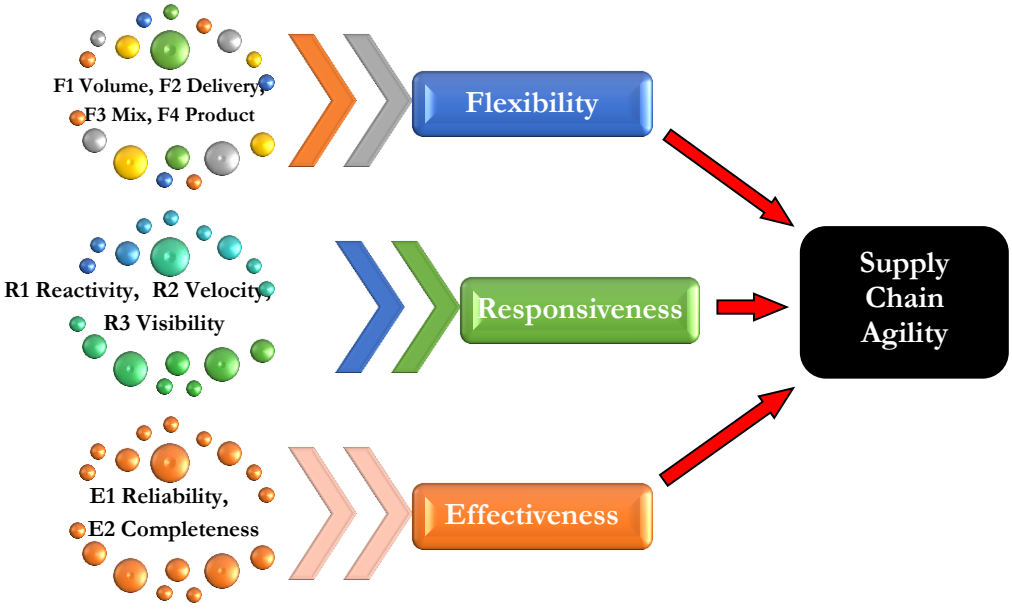

Figure 3 – Dimensions of Supply Chain Agility (adapted from Charles et al., 2010)

Supply chain literature (Power et al., 2001; Christopher & Towill, 2001; Yusuf et al., 2004) identifies Flexibility as a key dimension for supply chain agility. In humanitarian context, the sub-dimensions of Flexibility, namely, Volume Flexibility & Delivery Flexibility gain prominence (Charles et al., 2010; L' Hermitte et al., 2015; Beamon & Kotleba, 2006; Martinez et al., 2011; Gralla et al, 2014). Early phase disaster operations in dispersed island clusters and remote coastal regions implies field forces need to organize into self - directed work teams with minimal supervision and hierarchy, adapting to conditions of uncertainty and be flexible in its operations.

Often special disaster field force units are programmed to work under such conditions. This is because of the need to quickly adjust (ramp up) capacity, have built-in volume flexibilities to cater to vital demands (food, clothing, medicines etc. – refer Figure 4 for Humanitarian Supply Chain) at short notice. Such demands often emanate from cross-docks (high speed warehouse) handling large volumes and distributing relief material to shelter homes, relief camps or muster stations during early humanitarian operations phase. Strategic locations of Cross-docks in a network are imperative for effective distribution and quick response (Barsing et al., 2018), as they function as the *de facto* "fulfilment center" connecting inbound and outbound logistics. It is to be noted that unlike in commercial supply chains under normal conditions, or humanitarian supplies in mainland, early humanitarian operations in islands, particularly during peak cyclonic conditions come with a new set of challenges. First, inbound logistics from mainland to island territories is effectively cut off during the peak of the disaster. Second, the variety of material to be distributed at demand points need to be sorted, bundled and kitted from a safety stock or relief supply at a centralized distribution center (cross-dock). In such scenarios, the presence of a functioning cross-dock, in an island cluster often affects the volume flexibility of early humanitarian relief operations. Thirdly, the outbound delivery from distribution centers (cross-docks) in island territories and coastal regions is constrained by the number of last-mile-delivery vehicles (Balcik et al, 2008). A specific set of challenges arise in coastal regions and island territories, wherein access to end user is constrained by reach of last-mile-delivery vehicle from the supply hub or cross-dock. Often larger boats or ships, do not have higher draft (depth of water required to float) requirements in comparison to the water depths in shallow draft zones around the islands or coastal regions. Furthermore, the maneuverability of larger boats is limited in the narrow waterway labyrinths in coastal regions and island clusters. Helicopters, smaller boats (including motor powered ribs) thus become critical in last mile delivery. This has a bearing on delivery flexibility, which is the ability to make multiple deliveries at different locations in a region within a span of time. Within the island cluster, the stochastic demand patterns arising from demand centers require the supply chain to have delivery flexibility. It therefore follows from the above arguments that, the activation levels of functioning cross docks and number of last-mile delivery vehicles in island clusters affect the flexibility of early humanitarian operations, particularly on the respective sub-dimensions of volume flexibility and delivery flexibility. The hypotheses on flexibility dimension of early humanitarian operations are thus stated:

H3a: *Activation Levels of Functioning Cross-Docks in Island Clusters positively affects the Volume Flexibility of Early Humanitarian Operations.*

H3b: *The number and type of last-mile-delivery vehicles in the fleet positioned at the island clusters positively affects Delivery Flexibility of Early Humanitarian Operations.*

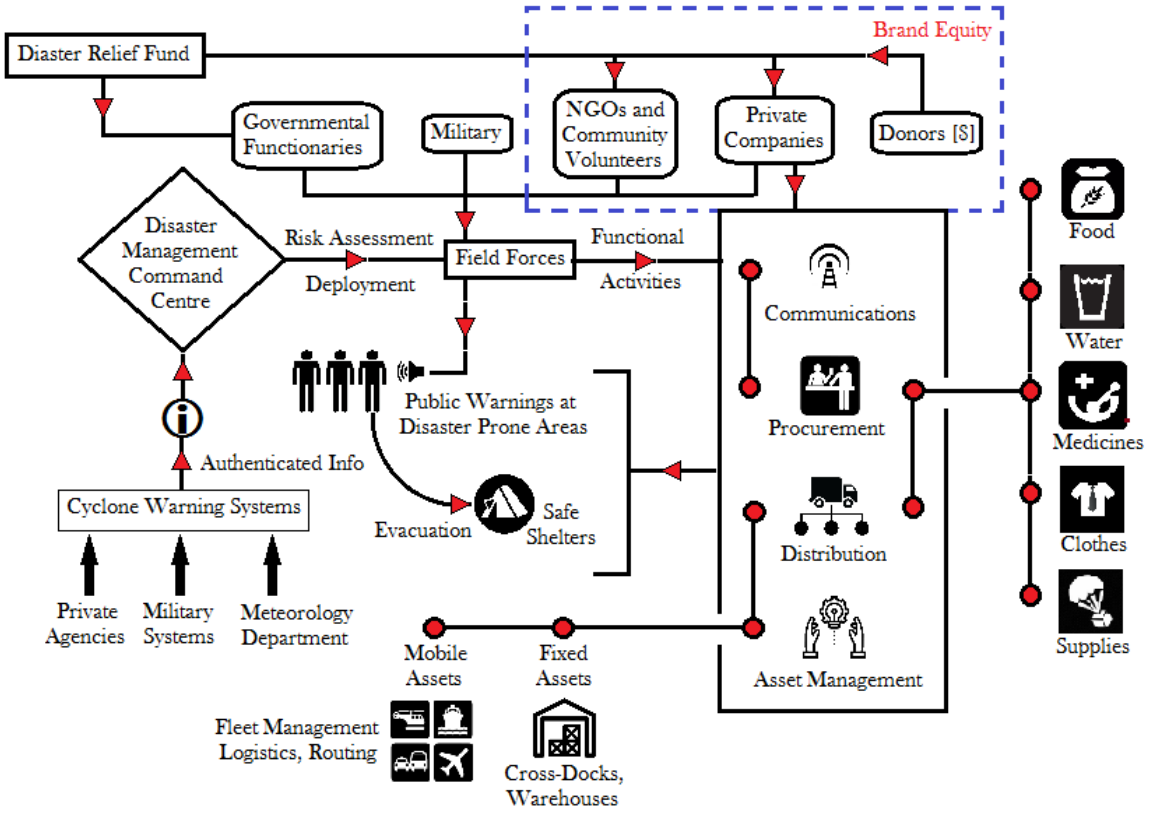

Figure 4 – Humanitarian Supply Chain

Humanitarian supply chains (refer figure 4) are complex, coordinated mechanisms formed from the amalgamation of multiple stakeholders with differing objectives. In this paper, we study the relations ships between different variables and constructs in the humanitarian context. First we study, the integration levels between information systems and field forces. From figure 4, it may be observed that multiple agencies (military, federal government controlled meteorological departments, and other private players) have their own dedicated information systems for observation, assessment and early warnings. However, it is often observed that the field forces deployed at site may not have their own in-house information systems. The trigger for search and rescue, evacuation etc. may be based on inputs from a partner in the humanitarian supply chain. For example, in India, during the Tropical Cyclone Ockhi, the field forces such as the Navy, Disaster Relief Force and Coastal police act upon the trigger provided from the information systems group of the National Meteorological Department. Although, the Navy has its own in-house Meteorological Systems, civilian evacuations are based on governmental requests after information authentication. Our first hypothesis explores the integration of information systems and field operations, as time lag in procedural formalities and lacunae in synchronization impacts the effectiveness of early humanitarian operations.

Secondly, the field forces, their machinery, equipment and assets are normally positioned at base locations. When disaster strikes, the access to island territories and remote coastal locations are usually cut off. This is due to high seas, rough weather and harsher operating conditions. Furthermore, early humanitarian operations such as search and rescue, evacuations etc. have to be done in the first eight to forty-eight hours. The responsiveness of the early humanitarian efforts is dependent on the ability for field forces to cover the needs quickly

(velocity of operations). In the second hypothesis, we explore the moderating effects of Standalone Nodal Resource characteristics in Island Clusters on the relationship between velocity and responsiveness. It is observed that during the blackout phase at peak of the disaster, relocating and mobilizing external resources to the island clusters is tardy, and affects the responsiveness of early humanitarian efforts in the isolated island clusters.

Thirdly, we explore the 'Flexibility' dimension within the agility construct. According to research literature (Charles et al., 2010), sub-dimensions of Volume Flexibility and Delivery Flexibility gain prominence in humanitarian supply chain operations than commercial supply chain operations. This is due to the need to exponentially increase the supply volumes to demand points of relief material during crisis scenarios. Also, the higher uncertainties associated with humanitarian operations over commercial operations imply that the variation in stochastic delivery distributions are much more, requiring higher levels of delivery flexibility. It is to be noted that new product and product-mix flexibility sub-dimensions do not take precedence in early humanitarian operations, as the focus is on survival and subsistence, rather than introducing novel products or bundling different types of product components. In this study, we explore the effects of activation levels of cross-docks in island clusters and last-mile delivery vehicles, respectively on volume and delivery flexibilities during early humanitarian operations.

With reference to Figure 4, our study studies the interaction between Information Systems and Field Forces, Effect of Standalone Resource Characteristics on Responsiveness (covering needs – Flood, Water, Medicines, Clothes, and other supplies) of Early Humanitarian Operations in Island Clusters, and Effect of Activated Fixed Assets (Cross-docks / Warehouses) and Mobile Assets (Last-Mile-Delivery-Vehicles) on Volume Flexibility and Delivery Flexibility, respectively. The methodology of the case study is described in the detail in the next section of this paper. While this case, as a pilot work, explores specific research questions related to early humanitarian operations in island clusters and coastal regions, the data from the study may also used to explain and validate extent theories in the domain of humanitarian supply chains.

METHODOLOGY

This research started in early December 2017, quite serendipitously. The author of this paper, at that time was working with a marine boat manufacturer as a research consultant, when there was a request from the Navy to join their team to assess the impact due to Cyclone Ockhi, and the damage it inflicted on property, assets and systems in Laccadive Islands in the Arabian Sea. Cyclone Ockhi had made landfall on 2nd December 2017 at Laccadive Islands, a territory of India located around 200 nautical miles west of the Kerala coast on the mainland. '*Laccadive Islands*' is the anglicized form of '*Lakshadweep Islands'*, meaning 'Thousand Islands' in local dialect. Cyclone Ockhi, developed from tropical depression to a 'Category 3 Hurricane' in less than 48 hours hitting a geographically dispersed island cluster, practically isolated from the mainland. This makes the complexity of operations 'most difficult' as per the classification of disasters (refer figure 1).

Before the field visit, there were several briefings with personnel in the Navy including 2 Commodores, Captains, officers, divers, and other members of the team. It was instructed during the brief that the visiting field researchers were not allowed to take pictures at site due to the confidentiality of sensitive pictorial information, but were allowed to make diagrammatic representations or take field notes (Van Maanen, 1998). The research questions at that point of time were broad: (1) To study the nature of humanitarian operations in island systems, with a

focus on information systems and field operations coordination, (2) To assess the operational characteristics of assets, their capacity, and responsiveness of standalone resources deployed at the island cluster, (3) To assess the extent of damage of fixed and mobile assets, and their activation levels in wake of the disaster.

We base our method on an empirical, grounded theory approach (Eisenhardt, 1989). While our case study is exploratory in nature, addressing research gaps related to early phase of humanitarian operations at island territories and coastal regions, the data collected during the research is explanatory (Dubé & Paré, 2003). Hence, our research data may also be used to reinforce existing theories and validate extant literature. While this pilot study is unique, in the sense, it addresses a peculiar set of challenges associated with early humanitarian operations in island territories and coastal regions; the data collected is qualitative, limiting quantitative analysis. The theoretical focus of this exploratory research is on agility and its dimensions during early humanitarian operations, which has been elaborated in the literature review.

The data was collected in three stages. First, during the field visit to Laccadive Islands from December 3 – 5, 2017, the author of this paper, who was accompanied by two colleagues from a marine boatbuilding firm, took notes of the briefings and discussions with consultants, officials at site, navy personnel and inhabitants at the islands. The discussions were semi-structured in nature, but connected to the broad research questions described above. At the end of each day, the three field researchers summarized the each day's discussions and the collated transcripts. The list of interviews conducted during the field visits, the respondent profiles and the codified themes from the transcripts are represented in Table 3. The first part of the data collection (Gersick, 1988) included observations of personnel with whom we interacted during the field trip. Data collection through multiple field researchers (Pettigrew, 1988) who individually collected information and then exchanged notes was useful in building holistic perspectives and limiting personal bias. The field notes were taken from observation and discussions with 17 respondents whom we interacted during the first week of December 2018.

The second stage of data collection was through in-depth personal interviews post the Tropical Cyclone. The interviews were conducted face to face from January 2018 to July 2018. While the field data from the first stage was archived and setup for analysis, the second stage of data collection proceeded, with some overlap between the two stages (Gersick, 1988), enabling refinement of research questions (Harris & Sutton, 1986). A total of 18 respondents representing the Navy, National Disaster Response Force (NDRF), National Meteorological Department, National Informatics Centre, State Fire & Rescue Department, Coast Guard, Coastal Police, Naval Meteorological Department, Non-Governmental Organizations, State Government Hospital Administrators, Army Medics, Search & Rescue Field Operatives, Private Companies with Meteorological Information Systems, Drone Manufacturers (Aerial Assessment), and 1 Navy Captain previously interviewed during the field trip, participated in the second stage of data collection. All the stakeholders who were interviewed were directly involved during the Early Phase of Humanitarian Operations related to Cyclone Ockhi, and the memories of the events in the past few months were fresh in their minds, and they could recollect case facts without the need for much probing. The details of respondents, including profiles and the codified themes from the interviews are represented in Table 4. During the interaction in the second stage, anecdotes, and themes for cross-case analysis (Miles & Huberman, 1994) from similar past experiences emerged from respondents. This not only strengthened the empirical validity and reliability (Eisenhardt, 1989; Benbasat et al., 1987) of the data collected, but also reinforced extent literature (Yin, 2017), providing a fertile ground for testing theories (Kuhn,

1970) particularly relevant to the research questions in focus, and refining and synthesizing hypotheses (Sutton & Callahan, 1987). The second part of the data collection process was performed by the author of this paper who during this period had joined an academic institute, and the two field research colleagues were pre-occupied with routine business at the boat manufacturing firm. The longitudinal data collected from the first and second stages, was archived and codified for within-case analysis and preliminary theory generation (Eisenhardt, 1989; Dubé & Paré, 2003). It is to be noted that the second stage of data collection included pictures of hardware, and equipment, supplementing transcripts, as there weren't restrictions in the type of data gathered, unlike in the first stage of data collection.

At this stage, a deficiency of this research was unavailability of direct empirical evidence for cross-case analysis. We had anecdotal evidence from respondents in stage 2 of data collection, about past experiences of similar case scenarios. But lack of empirical grounding for triangulation, using cross-case analysis, posed as a challenge on the epistemological basis for validity and reliability for theory building, until the fall of 2018. The third stage of data collection was performed in the months of August and October 2018, from direct personal experience, field survey and secondary sources. In the month of August, the state of Kerala, a southern state on the west coast of India, was hit by the greatest deluge in 100 years. The author was involved in early phase of humanitarian operations including activating cross docks, and distribution of relief materials in the coastal state. This was followed by a survey conducted in October 2018 in flood affected regions in Kerala. The survey was administered by 98 graduate students from the author's affiliate institution as part of the Flood Impact Assessment. One of the objectives of the survey was to capture the disaster response mechanisms in place and the agility of early phase of humanitarian operations, in coastal regions, islands and atolls. 1997 respondents participated in the quantitative survey representing a total of 7867 people from their respective households. This data was archived and used for cross-case analysis.

Another direct empirical evidence for cross-case analysis was from personal experience of the author. In the first week of October 2018, while in Florida, a Category 4 Hurricane "Michael" developed in Gulf of Mexico, the trajectory of which was projected to hit Florida Panhandle. We gained evidence of early humanitarian operations in islands and coastal regions, and some of the best practices in synchronization of information systems & field operations, evacuations, and agility of distribution systems in the 48 hours before "Hurricane Michael" made landfall. This triangulation approach through cross-case analysis is in line with research practice (Grütter et al., 2002; Lewis, 1998) for data validation, reliability (Koners & Goffin, 2007), formulating and extending theories (Eisenhardt, 1989).

Finally, we ground our observations and findings in existing literature, improving constructs definitions and relationships, building internal validity and sharpening generalizability. Bringing in more cases for cross-care analysis and theory testing is desirable until theoretical saturation levels. At this stage, we draw this research to a closure, providing research insights, managerial implications, limitations and future direction for research. These are deliberated in subsequent sections that follow, starting with the narrative of the case-in-context.

CASE IN CONTEXT: CYCLONE OCKHI

On November 28, 2017, on the South East coastal belt of Sri Lanka, a poorly organized disturbance with ill-defined low level circulation center developed amidst moderately warm weather tropical conditions. The Meteorological Department of Sri Lanka predicted heavy rains for the next few days, however, did not issue a cyclone warning citing insufficient data to that

effect. On the 29th of November, the storm organized into a depression, further developing into a deep depression and then gaining characteristics of a cyclonic storm – Ockhi. The storm tracked along the south and south-western coastlines of Sri Lanka, causing massive devastation in regions near Matara, Galle, Ambalagonda, and suburbs of Colombo. Gale force winds exceeding 80 kmph destroyed coastal infrastructure, disrupted power transmission lines, uprooted trees and obstructed mobility. On 30th November, Red Alert was declared in Sri Lanka with schools suspended, and search and rescue operations launched by the armed forces in conjunction with state agencies and Red Cross Society. By December 1, 2018, Ockhi intensified to Very Severe Cyclonic Storm (Category 3 Hurricane) moving up north under favorable conditions of cyclonic formation. It hit the southern states of Kerala and Tamil Nadu in India, causing extensive damages to structure and property. It is estimated that Kerala and Tamil Nadu suffered losses of about $2.3 billion and $2.0 billion respectively due to Ockhi, with total death tolls amounting to 245 persons, with 661 persons missing. The southern districts of Kerala namely Trivandrum and Kollam, and the coastal districts in Tamil Nadu, namely Nagarcoil, Kanyakumari, Thirunelveli and Tuticorin experienced torrential overnight rains with heavy winds uprooting over 550 trees and 950 electric poles. The Meteorological Department had issued warnings to coastal communities, and fishermen at sea were alerted to return to safety. It was reported that over 2500 people were evacuated from cyclone prone areas with the joint efforts of Navy, Coast Guard and state agencies, and over 400 fishermen stranded in outer seas were rescued. While few naval officers reported incidents of fishermen refusing to return to shores despite warnings, some members of coastal communities who were interviewed in the aftermath of the cyclone denied getting timely information or relief assistance. According to one of the doctors who work at a health center in an affected district in Kerala, “This situation is very grave. The infrastructure is severely damaged. Families are broken because people were washed away. This year the communities here had no Christmas. The social costs are very high”.

Ockhi, subsequently spread out to the west, into the Arabian Sea (refer Figure 5 for Ockhi Trajectory), and at the peak of its destructive power, with wind speeds exceeding 63 knots rummaged over Maldives and India’s Laccadive Islands in the Arabian Sea, in the wee hours of 2nd December, 2017. One of the authors, present at site in Laccadive Islands, 2 days after this event recounts the damaged embarkation jetty, fluttered road boulders, ripped-off building rooftops, and a thousand fallen coconut trees in the southernmost island of Minicoy. The scene with the fallen trees and devastated infrastructure reminisced the aftermath of a giant spinning top with peripheral blades that pulverized a beautiful tropical island. None except one Government owned PSU (public sector undertaking) cellular (telecom) operator was active. Cross-docking centers in the island (away from mainland) for distributing relief materials (food, medicines, clothes, supplies etc.) were to be setup. Several fishermen who were rescued by the coordinated efforts of Navy, Coast Guard, and Commercial Shipping Liners were brought to shore and attended to be medical personnel. In order to cater to the logistical necessities in the islands, the Navy re-routed it fleet from bases on mainland west coast to demand centers, including islands of Kavaratti and Kalpeni. While on the drive to take stock of some critically damaged site in the island, the driver of our jeep, who was present on the island, when Ockhi struck during the night of December the 1st, 2018 narrated, “We were sitting huddled in the hospital building. Trees were falling all over the place, and I was wondering when it was going to fall on us. Cows, goats and other animals were flying in the air, and big trees were being uprooted, and flown away by the sea wind. I never thought I’d see this day.”

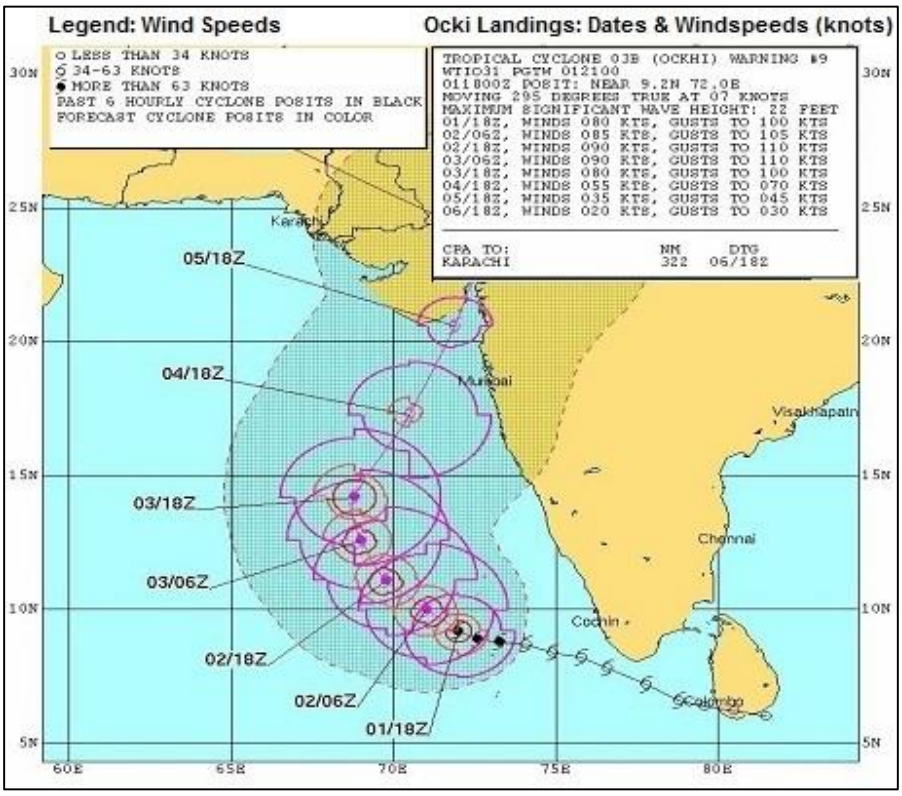

Figure 5 – Ockhi Trajectory

Source: Adapted based on information from Joint Typhoon Warning Centre (JTWC)

On December 3rd, 2018, Ockhi moved away from Laccadive Islands further westwards into the Arabian Sea, and into areas with no human habitations, and then drifted eastwards on 4th of December, heading towards the Gulf of Cambay near Gujarat on the west coast of India. Coastal cities such as Goa and Mumbai experienced heavy rainfall, which was unusual during this time of the year. While some areas reported of with coastal soil erosion due to Ockhi, other places near Mumbai reported ocean wastes dumped on the beaches by the cyclone. By December 6th, 2017, Ockhi subsided considerably due to unfavorable conditions near the subcontinent including high wind shear, and declining latency due to dry and cold wind from the mainland, which dissipated the storm as a low pressure phenomenon. Although, Ockhi was not a Super cyclone (Category 5) or Extremely Severe Cyclone (Category 4), it stands out as the worst Category 3 cyclone that hit the subcontinent in the last decade, causing more than U$ 5 billion of economic damages and 245 casualties and 661 missing people. The number of casualties or persons missing in the Laccadive Islands is not declassified, and not publically available.

KEY TAKEAWAYS FROM THE FIELD TRIP AND IN-DEPTH INTERVIEWS POST OCKHI

The research findings from the field trip to the affected areas and insights from the in-depth interviews with participating stakeholders are summarized in this section. Prima facie evidence from the field trip indicates that the operationalization of humanitarian efforts in the Laccadive Islands is problematic and crippled due to issues of access, communication, and mobility to the islands which is located around 200 nautical miles off coast of mainland India, in the Arabian

Sea. Severe Cyclonic activity imminently cuts off movement between mainland and the islands, necessitating adequate bunkers, and safe houses for island natives to take refuge when disaster strikes. Furthermore, adequate silos and cross-docking facilities (high speed warehouses) to store inventory and distribute supplies and relief material for the island cluster is essential. The case also throws light on the importance of agility of early assessment and evacuation response, which needs to be carried out in a few hours. This calls for higher level of synchronization between the information systems (MET agencies that handle forecasting, predictive analytics, and information diffusion) and operations on ground (field forces, including military, government agencies, humanitarian organizations and community volunteers). Flexibility in supply chains processes, including product mix, delivery flexibility and volume flexibility when multiple stakeholders are working together under the command of lead agency (in this case the military) are also key improvement areas.

It may be noted that while major urban metros like Kochi (in the state of Kerala) with geographical advantages, and are well connected with other supply-hubs command higher supply chain visibility (shared resources, information and tracking systems), other locations are often cut off during crisis situations. In our case, the remote villages in the southern districts of Kerala, and the Laccadive islands are effectively cut off from the cluster of hubs that activated during disaster scenarios. This calls for reorganizing of clusters so that humanitarian rescue and relief activity can reach out to remote locations as well, particularly with high population density.

Brief excerpts from in-depth interviews with some of participating stakeholders in humanitarian operations for Cyclone Ockhi are summarized below:

Military Personnel on the Field: "We can mobilize our forces at short notice. Early action in the first few hours is critical for the success of the operations. For emergencies, we have portable equipment, including mobile operation theatres, rehabilitation equipment, food and medical supplies that can be airlifted to base station from where we carry out the rescue and relief operations". Figure 6 shows some military hardware used for humanitarian operations.

Figure 6 – Military Hardware for Humanitarian Operations

Top Left: Mobile Operations Theatre; Top Right: Mobile Dispensary;

Bottom Left: Mobile Resuscitation Equipment; Bottom Right: Naval MET Forecasting System

National Disaster Response Force (NDRF): Units from 12 battalions of NDRF are deployed to crisis centers. The number of hierarchies in decision making is kept to a minimum for quick response. The Prime Minister of the Country is the Chair of the National Disaster Management Authority, and the Union Home Ministry connects directly with the State Chief Secretaries and the District Collectors for coordination and swift action. Over the last few years, the NDRF has been working with local communities to enhance disaster preparedness and to train volunteers.

Coastal Police: Operating under the state government, the Coastal Police has basic equipment like inflatable boats, life jackets etc. for basic search and rescue operations. Under relatively milder conditions such as depressions or heavy rains, the Coastal Police perform relief operations, and supports NDRF and military during more severe disasters, for which higher level of competency is warranted.

Fire & Rescue Department: Operating under the state government, the Fire & Rescue Department Unit normally attends to civilian emergencies such as Fire in a Building, Explosion etc. and provides safety clearance. While they perform tasks at district level, there is much scope in integrating operations with other forces, particularly in the area of information sharing and local support.

Meteorology Department & National Informatics Centre: The Meteorology Department is mandated to provide early warning and forecasts that are long term as well as short term (detailed and localized), and to alert the forces and other stakeholders to take early action. While in recent years, it has been difficult to accurately predict partly due to changing climatic

patterns, there has been serious flaws in synchronizing information systems and operations particularly with the state functionaries in the federal system. While the Meteorological Department works under the Central Government, the Police Force, and State Disaster Response Teams work under the state government.

Non-Governmental Organizations & Private Players: NGOs and private players such as retail chains, and commercial distribution networks have stepped forward as good corporate citizens in recent years, sharing resources including facilities to be used as cross-docks, and fleet for transport of goods, supplies and volunteers. Most of the work by NGOs and Private Organizations are in the relief, reconstruction and rehabilitation phase.

DISCUSSION AND CONCLUSIONS

The vitality of disaster preparedness and supply chain agility are the defining points of this case. The authentic relay of reliable information early enough by nodal agencies and the quick deployments of forces to alert affected areas, evacuation, and search and rescue operations can decide the fate of the operations (Day et al., 2012), and limit the magnitude of the consequences. Lack of coordination between central and state functionaries, in sync with the military and other critical functional machineries can also lead to delayed responses. In the case of Ockhi, while mass evacuations were effective in urban areas and its suburbs, particularly in localities such as Chellanam, Chellambararam, Kannamaly and Edavanakadu near the major port city of Kochi, mechanisms to evacuate were less effective in the hardest hit areas in the Southern Districts of Kerala and Tamil Nadu. Lack of preparedness in these regions, particularly the rural coastal districts can cripple disaster response efforts (Howden, 2009). The preparedness phase should include working with communities to build capacity and resilience to respond to a calamity, and to create public knowledge of evacuation options, pre-positioned emergency relief supplies and to work in coordination with participating agencies. The Joint Humanitarian Assistance and Disaster Relief (HADR) exercise conducted by the Navy in conjunction with central and state government forces, other participating agencies in April 2018, is a positive step in this direction.

The importance of hierarchical clusters for effectiveness of relief operations is noteworthy. In the case of Ockhi, while access to coastal districts on the mainland was possible, the islands were practically out of reach during cyclonic conditions. Even during normalcy, the commercial passenger and cargo liners are the sole lifelines of these islands which are no more than a few kilometers in length and over 200 nautical miles away from the mainland. The availability of robust cross-docking infrastructural facilities, and bunkers, which are resilient during harsh conditions are vital for flow of materials, people, and relief supplies (Ben-Tal et al., 2011; Barsing et al., 2018). Furthermore, the functional competencies of different players participating in the humanitarian operations vary. According to a retired Vice Admiral, “While the coastal police and stage agencies can handle emergencies of smaller magnitude such as tropical depressions or heavy rains, they do not have the logistical infrastructure to deal with hurricanes or events of higher magnitude. The armed forces are mandated to step in during such events. Even then, the NGOs, and community support groups have a role to play in implementing the centrally coordinated efforts at district and locality levels. We are conducting joint exercises to create awareness and enhance our preparedness.”

The role of private companies and willing donors in humanitarian efforts has been gaining significance in recent years. While the intentions of benevolent donors and volunteers are appreciable, it complicates the already complicated, urgent and important operations in an

environment that is uncertain, frustrating and at best chaotic. Factoring in selective and independent funding to specific disaster affected areas, avoiding duplication of efforts and making best use of all available resources from multiple agencies with varying objectives are difficult choices. While many private companies such as Facebook (Safety Check Feature), DHL (fleet sharing), Airtel (Communication Systems), Ola Cabs (LifeSaver in partnership with Apollo Hospitals) etc., work in partnership with UN agencies such as World Food Program (Food Supplies and Managing Depots), to mitigate, avert or to provide relief during disasters, the integration of functional competencies with nodal agencies has been a challenge. On the flip side, there have been cases where help during dire circumstances were refused. For example, during the devastating Yargis cyclone that hit Myanmar in 2008, the military regime refused aid and relief supplies in ships that were anchored off the coast of the Rakhine state. In a free economy, multiple forces are at play; while resources are precious and all-hands-available-on-deck are welcome to contribute in humanitarian operations, companies voluntarily contributing to the response, relief, and reconstruction efforts could experience an upside in their brand equity. Figure 4 represents a humanitarian supply chain with multiple stakeholders with varying functional competencies. While government functionaries and military work on a welfare state mandate, and obliged to provide relief, private companies may choose not to participate. During the Ockhi cyclone, certain private players partnered in the relief response, salvage and reconstruction efforts. While the benefits of these may not be immediate, sustained partnership may have an impact on the brand equity of these companies. While eyeing increased brand equity as the motive for volunteering may not be necessarily humanitarian, humanitarian necessities demand more corporate volunteers to share our humane responsibilities.

ACKNOWLEDGEMENTS

We wish to acknowledge the Indian Navy for facilitating the field visits and providing the logistical support to island territories. We would like to thank Xavier Institute of Management and Entrepreneurship for providing space and time to carry out this research. We gratefully acknowledge the helpful suggestions of an anonymous reviewer and comments from the associate editor the journal on an earlier version of this paper that helped us improve our work.

DECISION SCIENCES INSTITUTE
How Knowledge Arbiter manages AI and Human Assets in KiM

Pratim Datta
Kent State University and the University of Johannesburg
pdatta@kent.edu

ABSTRACT

Creating knowledge and transforming it into innovations is a daunting task. Expanding upon the KiM (Knowledge in Motion) Model by Datta (2007), we propose a semiotic view of the KiM model (S-KiM hereon). Using semiotics as the theoretical lens to define and segregate levels of knowledge, the questions we ask are as follows: What are the different levels of knowledge and how do they correspond with various levels of AI and human capabilities required to absorb and cycle knowledge within organizations? We use Knowledge Arbiter (KA) as a fictional firm to exemplify the cycle of knowledge transformation in an age of AI and Analytics.

KEYWORDS: Knowledge Networks, Case, Innovation, Tacit Knowledge, Explicit Knowledge, Intermediaries, Artificial Intelligence, AI.

INTRODUCTION

In the world of big data, large-scale analytics, and AI, there is a knowledge management paradox. Sticky knowledge, defined as the difficulty of disseminating tacit knowledge within organizations (von Hippel, 1994), is a bad recipe for companies. Sticky knowledge is confined and insular and does not contribute to knowledge sharing. while stickiness of returns implies retaining economic gains from "unsticking" knowledge without eroding competitive advantages from leaky knowledge. While the prosperity of firms hinges on identification, mobilization, and application of knowledge for sticky economic returns (Stewart 1997; Eisenhardt & Martin, 2000; Gupta & Govindarajan, 2000), the topic mired in fragmented and mired in anecdotes. As Davenport et al (1998) note, a failure to justify economic returns from KM investments often leads to an early demise of KM initiatives, leaving a bitter aftertaste. This issue is acute. Increasingly, it is becoming mandatory for firms such as Chevron and Mitre to document the return-on-investment for KM projects for maintaining executive sponsorship (Turban et al 2001). Interestingly enough, although research and practice have implicated that KM efforts are successful only when KM investments are linked to demonstrable performance viability, the underlying process is far from transparent. Unless organizations understand the key elements in the KM process, KM projects are likely to remain an ambiguous investment, and knowledge, an elusive asset.

LITERATURE REVIEW

Agents and Knowledge Management Research

Agents are autonomous entities that perform intermediation tasks on behalf of an organization. In the context of KM, agents are either AI software artifacts or human entities (autonomous people or groups performing prescribed intermediation activities such as Nonaka and Takeuchi's "knowledge-creating crew") embedded in organizational knowledge flows.

AI and human agents in KM promote a context congenial to the creation, transformation, sharing, and utilization of knowledge. For example, AIs can embody complex functions that scan, collect, and structure data into visual depictions (e.g. cross tabs, pivot tables, plots) without the need for the user to learn the complex algorithms used in translation. Similarly,

human agents (e.g. interpreters) allow speakers to make extempore speeches in their own language without having to worry about the complexities of translation. Together, AI and human KM agents increase process transparency by facilitating knowledge sharing and transfers, relieving the user of understanding inherent translation and conversion complexities. An agent-mediated KM process thus enables sharing of knowledge and provides newer, better, and more accurate interpretations (Nonaka and Takeuchi 1995).

Altogether, rapid advancements in AI has allowed for embedding organizational data, routines, and processes into routines, repositories, and functions- creating opportunities for time-saving, duplication of effort, and consistency through rule-based reasoning. In AIs, rules and constraints are built using logic statements that can be easily validated, managed, traced, and enforced while ensuring reliability and integrity. However, it is important to note that the process of embedding logic to create AIs is constrained by limitations of syntax in capturing the overarching domain of understanding. As a result, the original meaning is lost. Only the syntax can be stored, not the semantic nuances that makes knowledge management such a rich and complex phenomenon. In the same vein, a AI can only analyze cues that are a part of its code, failing to dynamically learn and interpret cues offered by changes in the immediate environment. In that regard, AIs are better at analysis rather than interpretation and reinterpretation of content (Kogut and Zander 1992; D'Adderio 2003). Formal and standardized descriptions are core to AI development- creating objectivity and consistency in input output scenarios. Yet, these same characteristics also limit the ability of AIs to reconstitute the 'hows' and 'whys' of the KM process.

Artificial Intelligence (AI) versus Human Agents

In studying agent-mediated decision support systems, Hess, et al (2000) provide a set of agent attributes as characteristic features used to delineate different types of agents. They are homeostatic goals, persistence, reactivity, mobility, intelligence, and interactivity. We use these attributes to characterize agents on three broad attribute domains: individual, social, and organizational. Individual attributes are suggestive of the personality of the agent; social attributes are suggestive of how agents can operate in digital and organizational networks and hierarchies; organizational attributes are suggestive of the position, power, and goals of agents in an organizational hierarchy. When juxtaposed, persistence, reactivity, and intelligence correspond to individual agent attributes; mobility and interactivity correspond to social attributes; and, homeostatic goal corresponds to organizational attributes. Together, these attributes can be used to define agent effectiveness[1] and provide support for the choice of specific agents in various phases of organizational knowledge management..

Organizational Domain: Homeostatic Goal
Homeostatic goal is an organizational characteristic. It is a goal-state that an agent can attain and maintain as long as required by the organization. A homeostatic goal-seeking characteristic allows an agent to reduce variance in knowledge transformations by constantly readjusting itself to maintain equilibrium indefinitely unless and until the organization goal is redefined (Covrigaru and Lindsay 1991). As an example, if an agent is provided a goal of securing orders from different entities, the agent is expected to keep trying to secure orders unless and until the organization redefines the goal. Nonetheless, while homeostatic goal are common, goal-seeking behavior differs between AI and human agents. A AI will indefinitely parse all incoming content based on certain pre-specified parameters to ensure accomplishment of its goal with little

[1] *Agent Effectiveness = f(homeostatic goals, persistence, reactivity, mobility, intelligence, interactivity)*

variance. However, the variance exhibited by a human agent is likely to be relatively higher, particularly because a human agents' embedded logic is not as standardized as in AIs. As a result, homeostatic goal-seeking behavior that may require reproducing previous routines in the exact manner may be more difficult for human agents to replicate. On the other hand, non-routine and complex organizational goals such as strategizing on innovations for achieving competitive advantage are likely to be better addressed by human agents.

Individual Domain: Persistence

Persistence is an individual characteristic that refers to the ability of an agent to exhibit a sense of durability and continuity relative to its immediate span of execution. To exhibit persistence, an agent is not required to be constantly active and can remain temporarily inactive or cryogenic state (Bradshaw et al 1997). Persistence differs between AI and human agents, especially in regards to retained memory. While both AI and human agents have (or can have) the ability to save to organization memory, the capacity and the type of memory is vastly different. Organizational memory consists of declarative and procedural memory (Anderson, 1983). Declarative memory is representative of content derived from codified documents such as blueprints, spreadsheets, source codes. Procedural memory, on the other hand, resides in complex social structures and practices. While AIs are better at building declarative memory, human agents seem to be better at building procedural memory.

AIs can build and access declarative memory, i.e., a memory for codified material structures and practices in documents, databases, knowledge management and intranet systems. While AIs can create, store, and parse vast amounts of extremely specific declarative memory with unparalleled efficiency, they are extremely limited at creating procedural memory, i.e. memory for social structures and practices embedded in complex and tacit interactions, communications, culture, and other innate factors.

Individual Domain: Reactivity

Reactivity is another individual agent characteristic that refers to an agent's ability to perceive changes in the environment and respond according in a timely and reasonable manner. The reaction must be in accordance with its homeostatic goal and offer a degree of persistence. AIs react faster to minute shifts because it is easier to incorporate a vast number of variables and response conditions within event handlers. While it is true that AIs are less likely to utilize small subjective social shifts, it is exceptionally robust in capturing small changes as long as they are codified or declarative. For example, a AI is can assign very specific date-time stamps to subtle changes in currency rates, allowing them react in an extremely short time-period. Human agents are likely to find it more difficult to map up such infinitesimal shifts and schedule immediate responses. As Hess et al (2000) note, agent reactivity is a stimulus-response scenario and does not require intelligence. As along as more and more scenarios and corresponding actions can be built into the control structures of event handlers, AIs offer a faster response schedule and are thus better suited to responding to external stimuli. However, it must be realized that predefined control structures can limit reactivity to a wide variety of changes that have not been built into the agent logic. In addition, a AI uses a predefined and objective response logic that may not lead to an optimal reaction. A human agent would better able to distinguish between marginal bid increases and make a more optimal decision.

Individual Domain: Intelligence

Intelligence in one more individual agent characteristic, defined as an enabling feature of reasoning that allows an agent to pursue homeostatic goals efficiently and expertly without assistance from the user or designer (Hess et al 2000). For conditions stipulating intelligence from a standard iterative process, AIs are likely to perform very well. However, human agents are better substitutes as process conditions shifts to a less systematic and more random series of actions that require reconstructing the 'whys' and 'hows.' For example, AIs can easily collect

and analyze user clickstream data to specifically map navigational history; however, unlike human agents, AIs cannot explain the 'why' behind user navigation.

Network Domain: Mobility

Mobility refers to an agent's ability to migrate from one site in a network to another in order to perform requisite tasks (Hess et al 2000). Mobility of human agents is marked by their capacity to adapt to heterogeneous entities and interact with them on an ad-hoc basis. However, because human agents lack a standardized logic, it is tougher for a human agent to preserve its state in moving from one interaction point to another. Human knowledge agents are also less durable than AIs and thus have an uncertain organizational tenure. In contrast, AIs are both durable and stable. Their mobility is achieved by transporting code embedded in routines and functions using distributed object services.

The growing popularity of web and object services (e.g. CORBA, DCOM), portable Java code, remote procedure calls, Object Management Group (OMG) naming, and component integration architectures (e.g. OpenDoc, ActiveX)) are enhancing AI mobility. AIs have a greater ability to preserve their state in the process of being transported from machine to machine. Human agents are more adaptive and flexible in seeking and interacting with emergent participants in a network. Human agents are particularly prolific in loosely coupled social networks that require constant recontextualization of interactions. This interpretive flexibility that can be used to support heterogeneous functions is harder to embed in AIs that relatively more formal and inflexible (D'Adderio 2003).

Network Domain: Interactivity

Interactivity is another network characteristic that marks the ability of an agent to maintain communication between different network sites and entities. In order to function, agents must be able to initiate and maintain dialogues with other entities in one or more networks, mainly by creating uniform communication structure and standards, also know as a common agent-to-agent interlingua or 'agent bus' (Bradshaw et al 2004). Like AIs, human agents, too, must speak the same language and share a common set of operations and structures for maintaining communication. While human agents are limited by their lack of common language and structure, human agents are much more flexible with their interactions and able to adapt and learn languages and structures over time. In addition, human agents can also initiate the use of a common interlingua such as mathematical notations, audio-visual cues, and models to mitigate the constraints posed by the lack of a single set of communication protocols.

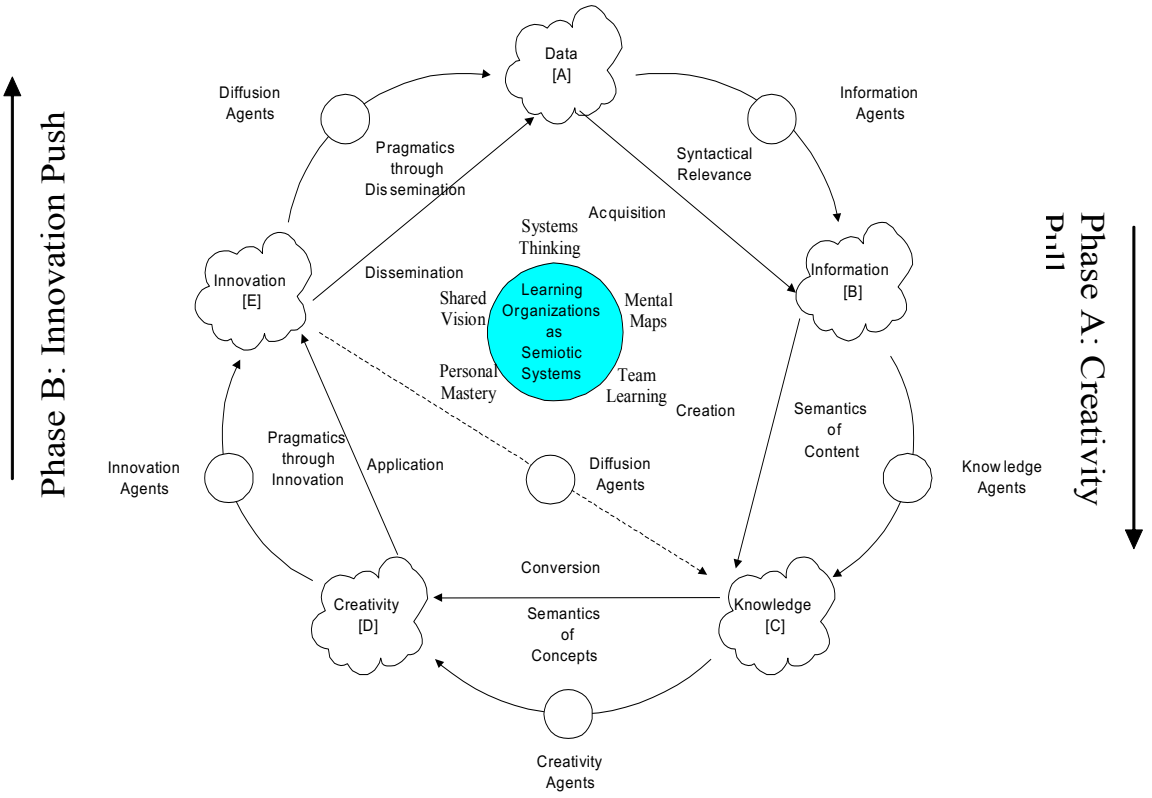
THE S-KIM FRAMEWORK AND THE CASE OF KNOWLEDGE ARBITER (KA)

We believe that knowledge management is a complex and multifaceted phenomenon that, when investigated using a single methodological paradigm, robs it of its richness and reality. The single method argument of paradigm incommensurability insists that researchers be captive to single set of assumptions stipulated by a specific paradigm of method, ignoring alternative cues from reasoning and reality. But, there is no single paradigm of method that captures the reality of KM. Knowledge is a multidimensional construct, embedded in workers, in the organization, in systems, and in processes; it is both objective and subjective, observed and experienced, assessed as a causal or a sense-making construct. Following Mingers' (2001) contention that "a richer understanding of a research topic will be gained by combining several methods together in a single piece of research" (Ibid: 241), we investigate KM using a cumulative, multimethod paradigm.

Data on best practices in KM was collected from a field study of six Fortune 500 firms over a period of a little over four months (Mid-November 2015 to Mid-March 2017). The criteria for site selection were drawn using the technique of theoretical sampling (Glaser & Strauss, 1967; Strauss & Corbin, 1990), a process by which a researcher selects certain informants and sites

based on theoretical relevance and purpose of the researcher. With respect to theoretical relevance and purpose, our site selection ensured a substantiation of KM efforts. The companies selected differ by sectors: one automobile firm, one biotechnology firm, two software firms, and two high-technology manufacturing firms. Each of these organizations was involved in KM and had, for over three years, invested and implemented KM systems to manage knowledge.

To mask firm-level differences, the S-KIM framework is exemplified using a fictional case of a learning organization (Senge 1990) called “Knowledge Arbiter” (KA) and envisioned as a firm that simultaneously creates and applies knowledge to reduce its innovation cycle. As a learning organization, KA believes in the five disciplines: systems thinking through the conceptualization of knowledge management as an interrelated multilevel system of transformations; mental maps where models are used as a representation of the KM phenomenon; personal mastery through the cyclical process of continuous innovation and knowledge; shared vision achieved by unsticking knowledge for creation and innovation; and team learning supported by agents to facilitate knowledge transformations through networking, dialogue, and dialectics. In summary, KA is informed by the best practices that constitute the S-KIM framework.



At KA, AI bots routinely access, filter, and validate its internal and external data sources and transform data into information. KA’s decentralized architecture allows data to be stored in federated warehouses rather than in a central location. KA’s federated data warehouse also allows other firms to link to distributed and heterogeneous data sources while maintaining network, location, and invocation transparencies. The criticality of this transformation phase lies

in the filtering and querying abilities of information agents who reduce terabytes of data into usable format.

Content as Meaning

Having generated information by filtering noise out of data, firms concentrate on transforming information into knowledge. According to Stohr & Zhao (1998), "Knowledge is the capacity to turn information into profitable action. Information, on the other hand, is data rearranged, sorted and aggregated so that it becomes suitable for input to a knowledge processor of some kind." At KA, executives understand the value of tacit knowledge. They believe that in order to share tacit knowledge, firms must try to interpret, articulate, and codify it into explicit knowledge. Truly, articulation of tacit individual thought processes and practices into more cognizant and replicable organizational processes is immensely valuable.

At KA, AI and human elements that make up the knowledge agents are synergistically bound. Knowledge agents conduct brokerage activities by searching, translating, and transforming available information into knowledge for future exploitation. These knowledge agents serve two purposes: to codify and to personalize (Hansen, 1999). KA uses a sequential strategy of codification followed by personalization in creating its knowledge database. Codification is a process by which explicit knowledge is created from information and stored in repositories for repetitive and routine querying. This process is carried out by KA's automated AI bots. Information generated from data, albeit relevant, is over-determined.

Concept as Meaning

To make knowledge actionable, organizations need to foster creativity as an extension of their base of knowledge (Dennard 2000). We define creativity as the inception of a new idea or perspective derived from a given knowledge base. Although creativity is often a result of combinations and re-combinations of existing but previously unconnected knowledge, it is a unique outcome—a knowledge artifact that extends and makes knowledge "actionable" and serves as a prerequisite for innovations (Von Krogh et al 2000; Sheremata, 2000). In applying existing knowledge to generate concepts that the organization can apply for economic returns, this phase is a first step towards sticking economic returns and "sticky" returns.

Once preliminary concepts are developed, KA organizes off-site creativity workshops where creative agents work intensively with individuals, groups, and subgroups to fill in the missing pieces and integrate concepts for creative synthesis. Final concepts are justified and systematically articulated in terms of feasibility (e.g. technical, operational, legal, and political), market appeal, and management priorities. These articulated and detailed reports are stored into an enterprise "concept base" consisting of product, service, and process concepts that are deemed to have future application potential. To summarize: in this phase, intensive interaction between tacit and explicit knowledge leads to collective reflections that are "finally crystallized into explicit concepts" by creative agents who instill idea-generation and help justify the value of such ideas and concepts (Nonaka and Takeuchi 1995: 86).

Conception to Commercialization

Transforming Creativity into Innovation: Pragmatic Sense-Making

In "The Frontiers of Management" Peter Drucker (1986) expounds: "[creative] ideas are somewhat like babies—they are born small, immature, and shapeless. They are promise rather than fulfillment. In the innovative company executives …ask, 'What would be needed to make this embryonic, half-baked, foolish idea into something that makes sense, that is an opportunity for us?'" From a semiotic standpoint, this phase deals with pragmatics concerning the use and outcome of creative concepts. Pragmatics asserts the need to increase organizational propensity to innovate by making their final concepts "actionable." Because knowledge is

localized, embedded, and invested in practice, it is only through its application as innovations can resolve limitations originating from inadequate and mis-specified semantics (interpretations) (Carlile 2002). In the process, concepts become more granular, valid, and justified as they are pushed towards commercialization. From converting concepts into commercial solutions to reducing resistance and putting concepts into action, the philosophy of pragmatics drives this transformation.

In transforming creativity into innovations, an organization needs the habitual assistance of another set of intermediaries: innovation agents. Innovation agents perform brokerage activities in the transformation process and have a vital influence in molding innovations (Henion, 1989; Strassmann, 1994). At KA, innovation agents are managers who evaluate concepts, assess feasibility (economic, legal, political…), allocate resources, and proactively assist in development and implementation efforts. Efforts from innovation agents, albeit driven by practical rent-generating aspiration, are carefully balanced in order not to compromise on innovation quality. Both the innovation outcome and process are mapped and documented by innovation agents into dedicated enterprise-wide innovation project databases. “In the process of turning innovative ideas into reality,” as Hargadon (1998:224) notes, mapping “[innovation] activities are invaluable because they generate a wealth of knowledge that’s a result of struggles, the agonizing way they went through to try to figure out what’s the right way to proceed.” At KA, the process of innovation is as important as the innovation outcome itself.

Diffusion of Innovations: Pragmatics of Dissemination

Innovations, although “sticky,” do not undergo obsolescence. Every innovation may be regarded as having a memory that incorporates its development and can be explicated as data in forms of patents, publications, and other materials that are disseminated via journals, trade magazines, academicians, and practitioners, among others. This is what is known as “innovation diffusion” (Rogers, 1995). Rogers (1995) describes innovation diffusion as a process by which an innovation is communicated through channels over time, leading to further unsticking knowledge and implicating the perpetuity of KM and the S-KIM framework. From a semiotic perspective, this phase is concerned with the pragmatics of innovation diffusion to further knowledge use and reuse, without compromising competitive advantage. Pragmatics realizes that innovations, like knowledge, are also localized and embedded in practice (Carlile 2002); selectively diffusing data from innovations once again reduces stickiness and signifies the pragmatics of reuse through dissemination.

Although innovation diffusion is an essential component in the S-KIM model, dissemination is never absolute but controlled. Diffusion agents, generally human, play an important role in controlling the innovation diffusion flow by internalizing mission-critical data while externalizing non-mission critical data. Disseminating mission-critical data can cost a firm its competitive advantage. At KA, diffusion agents periodically query and scan the enterprise innovation project database to delineate critical and non-critical parts of the innovation documentation into critical and non-critical parts. Non-critical parts of the innovation documentation are generally declarative and factual; critical parts of the documentation are generally procedural and cognitive.

DISCUSSION AND CONCLUSION

When organizations embark on KM initiatives, a common concern they face is deciding on a KM process that can lead to a fruition of their KM investments. Learning the process by which firms can secure “sticky” economic returns while maintaining the “non-sticky” or context-independent attributes of information and knowledge for continuous sharing and pollination is paramount to any successful KM. Addressing this concern, this paper combines technical and sociological

perspectives in KM research to present an agent mediated S-KIM process model informed by best practices. The objectives are met. The process of simultaneous sharing and appropriation of knowledge is explicated and empirically verified; contingencies are elicited by introducing the role and significance of agents in the transformation; and, finally, the S-KIM model is developed as a complementary agent-mediated KM framework.

This paper presents a systematic approach to unsticking knowledge and application. This paper also uses a process perspective that first draws from semiotics, information systems, strategic management, and organizational theory for theoretical support and then complements this support with current best practices to derive the proposed S-KIM framework for a holistic understanding of KM. This framework provides a unified perspective of the KM process by bringing together multiple strands of research and practice. Also, by striking a balance between theory and observation, the S-KIM framework lets us examine the complexities of resource transformations, agent-mediation, and event transitions inherent in the production and generation of "sticky" returns from "non-sticky" information.

The S-KIM model introduced in this paper may be extrapolated to organizations involved in KM and embodying structural devolution. As digital networks, globalization, and discontinuities in organizational environments propel organizations to substantiate collaborative "boundaryless" structures for seeking knowledge, and as harnessing returns from knowledge remain shrouded in ambiguity, there is a need to develop novel approaches that can breathe fresh perspectives into conventional KM paradigms. This paper is a step in this direction. The adopted approach synthesizes theory and practice to propose a new paradigm of actionable KM. The use of this approach here was particularly appropriate, generating critical insights and interactions that surface from the theory and practice of KM, elements that, to date, have remained fragmented or largely overlooked in KM literature. The S-KIM framework developed from these insights and interactions proposes a different approach to KM, promoting KM as a transitionally dynamic agent-mediated process that links unsticking knowledge and sticking economic returns . As creators, users, and disseminators of knowledge, researchers and practitioners should find the framework useful in their future quests to both explore and apply knowledge.

Structuration Analysis of Accounting-Based ERP System Organizational Change

Mostafa Hassan

samar@sharjah.ac.ae

ABSTRACT

Using Giddens (1984, 1990) notions of trust, agents' reflexivity, ontological security, dialectical of control and power, the study explores the implementation processes of Enterprise Systems known as ERP. The case study findings present that the accounting and accountability systems following the adoption of the ERP facilitated organizational members' reflexivity and critical reflection in re-assessing the pre and post ERP system ways of thinking. The findings also illustrate how trust (whether personal trust or system trust) plays a pivotal role in reinforcing the organisation power to change, and how the mistrust has become a source of power hindering organisational change.

KEYWORDS: ERP, customization, power, control, accounting practices

INTRODUCTION

This study examines the political behavior associated with the adoption of ERP in emerging economy country. The study extends on prior accounting-based ERP adoption literature that suggests that the ERP system has a limited or no impacts on accounting practices (Granlund & Malmi, 2002; Dechow & Mouritsen, 2005; Quattrone & Hopper, 2005; Kholeif et al., 2007; Cadili & Whitley, 2005; Hassan & Mouakket, 2016). For example, Arnold (2006) suggests exploring behavioral issues associated with the adoption of the ERP system. He suggests to examine: 1) how top management influence the adoption of the ERP system, 2) the processes of aligning organizational members' routines with the ERP requirements, and finally 3) exploring the (un)known motives of implementing accounting-based on ERP system. Chang (2014) recommends examining how organizational members' attempt to gain power, secure self-interests, and avoid responsibility is closely related to what he calls "political behaviour" during the information system development and adoption processes. Coad and Glyptis (2014) highlight that people political behaviour rests on the feelings of mutual trust in which people trust others and trust the system they use on daily basis, while Busco et al., (2006) believe that human political behaviour is an outcome of a balance between control and trust in business corporations.

The above studies concluded that future research should address how accounting practices are impacted by the interplay of conflicting interests of developers, users, and customers. They also identified the need of a solid theoretical framework to investigate how social structures, culture and agency are intertwined while capturing the diversity of agent interests. Our study addresses this research gap and examines a transforming public organisation employees' politics, trust, and control through a theoretical framework informed by the lens of Giddens (1979; 1984; 1990) structuration theory and his notion of trust. The study, therefore, contributes to prior studies in

several ways. The study is one that contributes in examining human political behaviors in an emerging market. The study contributes to prior studies which examine the effects of ERP systems on individuals (El-Sayed, 2006; Jack & Kholeif, 2008). The study also contributes to Fincham (1992) and Hardy (1996) frameworks of power since they do not underscore the power of "trust and/or mistrust". The empirical findings showed how trust is intertwined with Fincham (1992) and Hardy (1996) frames of power and what are the pillars that lie behind organisational trust and/or mistrust through the lens of Giddens' (1979, 1984) structuration theory. Following this introduction, the study critically reviews prior studies, discusses the theoretical framework, the methodology and the data collection methods. Then the study presents evidences from the case followed by some conclusions and implications that provide suggestions for further research.

LITERATURE REVIEW

The ERP system is an integrated enterprise-wide computing system. The system is a set of integrated software programs which are named as modules (Scapens & Jazayri, 2003). It automates business processes, shares common data across the organization departments and produces real-time data (Brignall & Ballantine, 2004), thus it improves the decision-making process, planning and control (Davenport, 1998). One of the key aspects of the ERP system is that the system includes the industry best practice in a computerized form. Another key aspect is that the system integrates traditional accounting transactional activities with processing activities associated other functions such as production, human resources management, and sales (Dillard, 2000; Dillard et al., 2005; Dillard & Yuthas, 2006). Under the ERP system, integration means that the entry of data in one software program (module) affects the data and the operations of some or all other software programs (modules) included in the system (Brignall & Ballantine, 2004).

The consequent of ERP implementation, therefore, would be changes in the individuals' behaviour. Yet there is paucity in the academic literature examining the political behaviour of organizational members involved in the implementation of the accounting-based ERP system. Scapens & Jazayeri (2003) examined the implementation of the ERP system at a division of a multinational American organization. They concluded that accounting-based ERP system organizational change has four attributes: integration, standardization, routinization, and centralization. These attributes, they argued, led to changes in organizational and accounting practices in the following ways: routine tasks were eliminated, line managers required more knowledgeable employees, and decision-making processes needed to be centralized in the hands of those who had access to the ERP system's shared databases.

Caglio (2003) examined the impact of an ERP on the roles of accounting and accountants for listed firm operating in Italian context. Caglio (2003) noticed that the ERP systems provided accountants with wide organizational knowledge, which, in turn, enabled them to be in charge of the organization's information systems. Quattrone & Hopper (2005) examined the how integrated system have had an impact on the distance between headquarters and branches. They argued that the use of relational (shared) databases eliminates the distance between the controller (headquarters) and the controlled (braches). They found that only one branch used the ERP system and the changes in accounting and accountability is due to functional prohibitory.

Yeh & OuYang (2010) carried out an exploratory case study of an ERP system adoption in a Taiwanese organization. Their study illuminates the cultural and political tensions raised during

the process of implementing the ERP system. They suggested that there is a need to balance power across different groups inside the organization during the processes of implementing the ERP system. Silva & Fulk (2012) examined the organizational power and politics in the Gulf Coast University where an ERP system was implemented. They explored the organizational members' political behavior through using Clegg's (1989) circuits of power to identify how the disturbances to the circuits of power create arise tension, and intensified to be power struggle, during the adoption of the ERP system. Chang (2012) explored how the manager of the Management Information systems department, depending on his expert knowledge in IS, adopts political tactics to achieve his goals of self-interest in information system development processes. Chang (2014) adopted a qualitative case data collected from an organization to analyze political behavior patterns during the information systems adoption processes. Based on Giddens' Structuration Theory (1979, 1984), Chang (2014) identified different patterns of political tactics when implementing a new information system and explored how these patterns interact and affect the organization and the outcome of the information system.

The above studies highlight the importance of revealing the political behaviour of organizational members linked to accounting-based ERP organizational change. The human actors political behaviour is rarely explored in emerging economies and how such behaviour emerge and formed is not yet fully explained by prior studies (Rom & Rode, 2007; Nwankpa, 2015). Prior literature does not examine the political behaviors associated with the adoption of the accounting-based ERP system organizational change. This study addresses this research gap and examines how patterns of political behaviors emerge during the interaction of a number of individuals as the result of adopting an accounting, accountability and ERP in an emerging market economy.

STRUCTURATION THEORY FRAMEWORK

Giddens' concepts of power and dialectical of control

Giddens (1979; 1984) argue that individuals have a capacity to change and achieve their goals when they use allocative and authoritative resources of power they possess. Allocative resources involve the rights of some individuals to hold command over material objects (e.g. factories, computers, information and ERP system) as well as knowledge of how to operate them (e.g. experience, skills, know-how) (Giddens, 1984). While authoritative resources comprise the rights of some individuals to command others to organize and co-ordinate the activities of other individuals. Giddens (1979) argue that power is a multi-directional and incorporates both freedom and collaboration representing *"dialectic of control"* which acknowledges the asymmetrical distribution of resources among members of social system (i.e. organization). This shows "subordinate" will have power such as means of production, skills, knowledge, experience which they can use to influence the actions of their "superiors". For example, accounting-based ERP system is designed and implemented to constrain the behaviour of subordinates, yet those subordinates have the potential to manipulate the system during the customization processes to their advantage.

Trust and agents' psychological make-up

There has been a number of scholars defining trust which is a concept that has been widely explored in the management literatures (Bachmann, 2001) and is also discussed in the accounting literature (Busco el al., 2006; Busco, 2009; Coad & Glyptis, 2014). For the purpose of this study, the conceptualization of trust is linked to what Giddens (1984) calls the agent's psychological make-up and the agent's need for routinization and ontological security. These

concepts incorporate a preference for a stable and predictable environment as well as the avoidance of the anxieties of change. Accordingly, trust is a mechanism that can increase coordination, reduce uncertainty and ease the functioning of organization and its accounting and accountability systems through the behavior of social actors, i.e. organizational employees (Bachmann, 2001; Busco el al., 2006; Coad & Glyptis, 2014).

Different scholars argue that the *routinization of activity,* and accounting and information systems routines are no exception, is the storage of organizational know-how and the creation of the feelings of trust (Busco et al., 2006, Busco, 2009; Coad & Glyptis, 2014). Organizational routines play a pivotal role in raising the feelings of trust across organizational members (Busco et al., 2006). Since systems are designed with an aim to fulfil management and sustain trust or otherwise. When the accounting systems sustain organizational routines, they are likely to support the organizational members' "confront zone" which is a necessary condition for the feeling of being 'safe'.

To Giddens (1979; 1984), agents are look, examine and evaluate others' and then "respond in term of the implicit stocks of mutual knowledge". Giddens (1984) defines this monitoring process by "agents' reflexivity" and argues that individuals' reflexivity rests on individuals' unconscious level. That motivation, Giddens (1984) states "maintain *ontological security* which refers to the individuals' need for regular social encounters to avoid anxiety". Giddens (1984) stressed on the importance of routinized behavior. Social systems, i.e. organizations, cannot exist without trustworthy routines (Coad and Glyptis, 2014). To some trusting is a major mechanism to control and coordinate. Giddens' (1984) comments on the significance of trust is neither based on the interaction between ontological security in the face of risk and uncertainty, yet it depends how individuals accept predictable routines. Trust is found in the deepest layer of ontological security (Giddens, 1984, p. 53). Trust, therefore, is described as an assumption of the continuity of that with which we are familiar, and is evident in the institutionalized routines. For Giddens, trust is defined as "confidence in the reliability of a person or system, regarding a given set of outcomes or events" (Coad & Glyptis, 2014).

When individuals change their organizations towards what they see as "something better", the role of trust becomes at the forefront. The complexity embedded in the process of organizational change requires what Giddens (1990) calls "personal trust" and "system trust" (Busco, 2009). Giddens' (1990) argues that trust rests on the intertwined across individuals. It addresses both the system and the individual with each is having their own view and familiarity with trust. Trust may be also rest on what is called as "system trust" which is the dependability and reliability of functioning of certain systems. It also does not requires individual face to face discourse and exchange of knowledge. There are two types of tryst that Giddens (1990) highlights: system trust and personal trust. The former is trust in principles, such as ERP technical or professional knowledge. This knowledge is always a kind of guaranteeing human expectations. Giddens (1990) equates this trust in the system with the trust in human and also equated abstract systems with societal and organizational institutions. These institutions take to form of a number of practices such as legal, educational, political and professional bodies. In this respect, confidence in accounting, accountability and auditing practices build in the ERP systems are both examples of systems trust. Trust, therefore, can be interpreted as the processes (Coad & Glyptis, 2014). This study examines how the accounting-based ERP organizational change has created uncertainties, or disrupted what Giddens (1984) "ontological security", and consequently make organizational members to cast doubts on the trustworthiness of the trustee.

METHODOLOGY AND DATA COLLECTION METHODS

This study utilizes an interpretive case study methodology (Scapens, 1990; Yin, 1994). The data collection methods included semi-structured interviews and documents. Date was collected during 2009-2010, and there were some follow up interviews during 2011. For confidentiality, authors name the organization undergoing the change as "Alfa". The depth understanding provided by the case study methodology enables to reveal the complex interactions between organizational members and the ERP.

RESULTS: THE CASE STUDY ANALYSIS

Since its inception, "Alfa" purchased an accounting system, named "Delta", to automate the processes in the Finance Department (FD). Delta was supplemented with another software named as Logsis to provide a full account of the required accounting information. A fundamental problem was the weakness of these systems' database. The MIS Department System Administrator stated:

> *"Data security under is the most important element to consider here."*

Because of the above weaknesses, "Alfa" decided to adopt the ERP system. Alfa top management used the language of efficiency, associated with the advanced technology to convince "Alfa" employees to adopt the ERP. For "Alfa" top management, the ERP system will cut cost. The automated system is expected to reduce costs The CEO stated that:

> "*We had to deal with the new ERP system problems because they are very important for the image of our organization."*

"Alfa" had two ERP project managers, first, a Project Manager (PM) affiliated to the steering committee and oversees the adoption of ERP system, second, the ERP system Manager affiliated to the FD and oversees the accounting-based ERP system customization problems. Giddens' (1984) notion of "dialectic of control" is evident here as shown in the above situations. The ERP system manager's accounting technical knowledge and the FD "know-how" of "Alfa's" accounting routines become, as Ocasio (1999), a source of organizational *inertia* and a guide for organizational *transformation* and change. Both used their power, i.e. technical knowledge and "know-how" of the accounting routines, to shift the accounting-based ERP adoption processes from the hands of the PM to their hands, i.e. FD and ERP system manager. The FD holds Alfa's "know-how" which is embedded in the organization's routines. The ERP system manager possesses the technical "know-how" and solutions of accounting-based ERP system customization problems. In fact, both have the power to deal with the organization's uncertainties resulted from the adoption of ERP system accounting module. Yet the PM utilized his hierarchical authority to bring back the power s/he lost. The Head of FD mentioned:

> *"The project manager rejected an access to the ERP. Consequently, the system manager became authority becomes very limited."*

Alfa routinely applies the UAE governmental accounting rules. Once the ERP accounting module is introduced, the FD employees raised many concerns about that module because it does not match with the existing governmental accounting routines. The ERP system Manager stated that:

> *"Fund accounting was not available in the old system. It is a unique feature in the ERP finance module. Users had problems with this new feature. They resisted that new feature because their responsibilities will increase."*

One FD employee gave an example of how "Alfa's" accounting routines were kept yet circumvent around the new module. Alfa's employees had personal and system mistrust because the system problems, the ERP system database security, and the controlling processes. The system manager stated that:

> *"Reprocessing was required. Departments requested too many missing functionalities that the system has to incorporate."*

On the one hand, the ERP system experts (PM and ERP system manager), see that the customization level is very high at the FD. On the other hand, FD members believe that those experts do not have the accounting background, and therefore they should not trust what they say. The above quotes show that Alfa's employees questioned the technical knowledge of the ERP system PM who represents what Giddens (1990) calls an *access point* to the system. Furthermore, FD employees through their face-to-face contacts with the PM and ERP system manager did not feel that the ERP system is a trustworthy one. Their trust in the ERP system was undermined, and therefore they were the subject of what Giddens refers to as "ontological insecurity". The RD employees had a number of technical complaints that casted doubt on trustworthiness of the ERP system. One mentioned:

> *"The ERP system module does not keep historical records of activities performed on the customer account. The system only keeps the results of the last transaction performed."*

A Customer Officer, in the RD department, raised another major issue related to the number of screens/windows/interfaces which must be competed to finish a single task. The Head of RD also expressed:

> *"Logsis was a much better system. We have never trusted the ERP system module. Until now, we double check every output from the ERP system module because we are not sure whether the figures are correct or otherwise. Some mistakes were found in the ERP system module output. We still rely on Logsis as a reference point to check customer accounts established before the execution."*

DISCUSSION AND CONCLUSION

The case study findings provide insights that inform: 1) how the object of change (accounting-based the ERP) is acted upon as a system of trust; 2) how forms of mistrust implicated in the adoption of accounting and integrated information systems; 3) how the new system altered the power relationships across Alfa's employees and 4) how the new system intermediated and provoked employees' feelings of trust and control during the customization processes. The case study evidence shows that the accounting-based ERP system created a discomfort episode, which facilitated Alfa employees' reflexivity and critical reflection in re-assessing the pre and post ERP system ways of thinking. The accounting-based ERP organisational change enabled Alfa employees to reflect on the processes of change and to assess the trustworthiness of the new system, the motives behind the transformation processes and consequently assessing the risks associated with such transformation. To recall, Alfa's top management purposively imposed the new system to create a new business image. The top management had a trust on the new system expressed in the languages of efficiency, effectiveness, cost reduction, single shared database, systems integration and improved performance and acted on this trust to make sense of its decision to adopt the accounting -based ERP system. Nevertheless, these

causes of trust turned to be sources of mistrust in our case organisation. To recall, the ERP system is costly to adopt, required highly skilled and knowledgeable employees and lack many operational benefits promoted under the banner of “automation” such as better data security and less workload.

The case study findings show the intertwined relationship between accounting-based ERP system and feelings of trust during the processes of organisational change. The new system created a complexity and uncertainty across Alfa’s employees because it requires system users to have the knowledge which they do not possess. To recall, Alfa’s employees lacked the technical knowledge of accounting-based ERP system, the ERP system PM lacked the technical knowledge in accounting, and this situation created feelings of uncertainly, organisational instability and consequently mistrusting in the new system. Alfa’s employees questioned and mistrusted the top management motives for change. To recall, they felt that top management motive for ERP change is to reduce costs through downsizing and reducing manpower (i.e. labor).

Although the study contributes to researchers interested in investigating political behaviour during the adoption of accounting-based ERP system, it has some limitations that provide opportunities for future research. First, the study explored how top management was persistent in its approach to implement the ERP system in a short timeframe, yet it is of importance to explore the effects of adopting the ERP system on users’ attitudes after a period of implementing the new system (i.e. longer timeframe effect). This exploration goes beyond the current study and represents an area for future research. Second, the study paid attention to “Alfa’s” employees’ political behaviour and their feelings of trust and control. Further research is recommend to examine the same yet across different stakeholders, inside and/or outside the organisation, interested in the adoption of ERP systems. Third, the study is a case study in emerging economy, the UAE, and therefore with limited generalization of the study findings. What mitigated this limitation is that our study is unique in that it has shown how power, trust and control are intertwined during accounting-based ERP system adoption in a non-Western context. Hence, our paper contributes to the limited number of studies exploring the political behaviour associated with the adoption of the ERP systems in Europe and North America. A direction for future research is that to compare the system adoption across different countries with different cultural values.

The study has a number of implications to the understating of power, trust and control during organisational change. The case study has illustrated how trust (whether personal trust or system trust) plays a pivotal role in reinforcing the organisation power to change, and how the mistrust has become a source of power hindering organisational change. To recall, the power of trust/mistrust lies on the individuals’ need for ontological security and uncertainty avoidance while being able to critically reflect, understand, monitor and evaluate what is going on during the process of organisational change. Trust, therefore, is a basis of power yet it is not necessarily sufficient to achieve the intended outcomes. Trust is understood as processes which incorporate both the causes and consequences for the human actions. This study has shown this dynamic view of trust and has contributed to the understanding of intertwined relation between trust and control and how they interact with each other outcomes during accounting, accountability and ERP system processes of adoption and adoption wherein multiple individuals become involved in networks of trust relations.

Researchers interested in organisational power can build future research upon our contributions in the context of accounting-based ERP systems. They can draw on our work to get a better

understanding and appreciation of how political behaviors emerge and intensify during the adoption of accounting-based ERP organisational change. In this regards, this study pursued a line of critical management accounting research which connects empirical findings to a theoretical framework informed by Giddens (1979, 1984, 1990) while explaining paradoxical findings (Alawattage et al., 2017). Although the study relies on structuration theory, the theory is not free from criticisms. Critical realists criticize Giddens (1979, 1984) structuration theory because of its conflation of structure and agency and his resolution by offering the concept of "duality of structures". What mitigates this criticism is that this study examined the "the position-practice relations" advocated by Ashraf and Uddin (2015) yet informed by Giddens notions of trust, ontological security, agents reflexivity, dialectical of control, agents knowledgeability and capacity to change through allocative and authoritative resources. Future research can pursue similar line research relying on Giddens' (1979, 1984, 1990) notions yet informed by critical realists approach.

Student Perceptions and Insights on the Selection of Information Technology as a Major – A Pilot Study

Kenneth J. Sousa, PhD
Bryant University
Email: ksousa@bryant.du

ABSTRACT

The demand for STEM-based positions continues to increase significantly. At the same time, the lack of availability of college-educated students entering the marketplace for these positions creates a recruiting challenge for employers. For decades, females have avoided majoring in technology during their higher education process. Even considering the starting salaries, number of positions and career advancement of a technology career, the number of females entering a technology career has not increased. This research compiled the perceptions of various indicators associated with first-year college students for analysis.

KEYWORDS: Career, Technology, Higher Education, Student Perceptions

INTRODUCTION

Background

The purpose of higher education institutions are to provide quality, skilled labor to business organizations. Students graduating from a higher educational institution and entering the labor market for an entry-level job usually have selected a career choice. Most career choices require a specific declaration of a major (and/or minors). For example, a student who desires to secure a position as an auditor will graduate with a business accounting degree; not a bachelor of arts in sociology.

However, there are many challenges before high school graduates begin their higher education journey. Unfortunately, in recent years, students are not engaging in career exploration and research. Colleges are encouraging prospective and entering students to “find themselves” by remaining “undeclared” for their beginning years in higher education.

Over the last decade, the use of technology has moved from the “back house” of businesses to the “front house”. The invention of … basic hardware devices such as laptops, tablets, smart phones … human-networked devices such as Internet of Things, voice assistants and smart home connectivity … and the consumer-faced applications such as social media, e-commerce and gaming … have all tightly integrated the functionality and social connections of our daily life with technology.

Coincidentally, students do not have a positive attitude or perception of information technology careers (Johansson, 2009). The National Academy of Sciences (2007) found that the percentage of high school students who express interest in becoming a scientist or engineer has sharply decreased. NAS believes that this trend could lead to fewer than 2% of U.S. high school graduates eventually receiving STEM degrees from four-year colleges and universities.

The issue? The decreasing interest in majoring in STEM based majors creates fewer graduates with the skills and knowledge necessary to promote technological innovation as well as the economy of the United States remaining competitive in an international marketplace.

This historical explosion of technology advancement requires skilled labor to design, build, test, manufacture, market and service information systems products. In addition, these professionals also require the ability to compile and integrate a successful strategic model to drive, expand and monitor the technology adoption fever for businesses. So the ability of labor, hopefully, skilled labor, is a critical factor for business organizations to manifest and realize the benefits of technology integration.

Research Objective

The purpose of this research is to identify the various influential characteristics on the intention to select information technology as an undergraduate major and, therefore, a career. For this initial research project, the insights of first-year undergraduates will be explored by gathering data through a survey instrument. The data will provide some knowledge on any influences relating to gender.

LITERATURE REVIEW

Labor Demand and Availability

Historically, U.S. businesses have encountered shortages of available information technology professionals for decades. In 1996, the Information Technology Association of America (ITAA) found that IT companies had about 190,000 unfilled IT professional jobs due to a shortage of qualified workers (Freeman, Aspray, & Computing Research, 1999). According to a 1999 Department of Commerce report the total number of IT professionals will grow to 2.6M in 2006; a 73% increase from 1999 (Handel & International, 2003).

The U.S. Bureau of Labor Statistics most recent data reports 6.25M computer-related positions in 2016; a large expansion over the 2006 estimate projections. As shown in Table 1, the outlook over the next decade reports an average change of 9.1%. It should be noted that while the BLS report has shown a decrease in the traditional computer programmers, there is a clear and rapid projected increase in software developers (applications and systems software) over the next decade. The application development category depicts the increase in applications for the various devices of tablets, IOTs and smart phones.

Occupational Description	Employment (in thousands) 2016	2026	Change, 2016-26 Number	Percent	Openings Annual Avg 2016-26
Computer and information research scientists	27.9	33.2	5.4	0.2	2.5
Computer systems analysts	600.5	654.9	54.4	0.1	44.9

Totals	**6,254.6**	**6,821.5**	**566.9**	**0.1**	**348.9**

Table 1 – Employment Trends in Information Technology Careers (https://www.bls.gov/)

Ironically, with all the discussion about shortages in technology professionals, the dominance in the marketplace is clear. According to the Census Bureau, the number of total information technology workers has expanded from 450,000 in 1970 to 4.6 million in 2014 (Beckhusen & Bureau, 2016). In the same period, the percentage of the civilian workforce has increased from 0.6% to 2.9%. The percentage doubled between 1990 and 2000 (1.2% to 2.5%). The increase in workforce could be attributed to the use of technology by e-business adoption as well as increased use of technology in small and medium sized businesses.

These increases are notable. However, it is more interesting to observe the radical change in the various positions and specialties within the information technology. In 1970, only three positions were identified; analysts, programmers and “other” (Beckhusen & Bureau, 2016). However, over three decades later, the number of positions skyrocketed to eleven; an increase in 267%. The expansion in the various technology positions reflects both the increase in complexity of managing the function within a business as well as increased specialization of duties and responsibilities.

Higher Education and Information Technology

The ability to project labor shortages can often be trended by using data from higher education institutions. While new entrants to information technology careers can pursue various post-high school alternatives, the greater majority of information technology professionals are being supplied by higher education.

According to the U.S. Department of Commerce, the number of computer science degrees between 1978 and 1986 increased to about 50,000 from 5,000 (Handel & International, 2003). However, the number graduates declined and remained constant in the early 1990s (approximately 35,000). The gender disparity associated with computer science graduates is more concerning. The availability of females available for entry-level information technology positions with a college degree is low. While females comprise approximately 60% of college graduates, only 18% complete their degree with a computer science major (Moore, 2015).

Gender Roles in Information Technology

Many studies have been compiled to understand the role of gender as it relates to attitudes and thoughts on technology (and STEM) careers. The negative perception of females on STEM focus on lower self-efficacy, intellectual and practical interest (de Vries, 2005; Endepohls-Ulpe, Ebach, Seiter, & Kaul, 2012).

At NASA, the number of aerospace engineers are men while less than one third of the agency's engineers are women (Moore, 2015). The Census Bureau reports that the U.S. civilian workforce of female information technology professionals trails all occupations substantially (Beckhusen & Bureau, 2016). From 1970 to 2014, the percentage of female workers for all occupations as compared to information technology was 47% to 25%.

The research relating to gender inequity in technology-related careers (and probably STEM-based jobs in general) suggests various causal possibilities ranging from violent electronic games or a boring view of programming (Anonymous, 2000). However, it is ironic that many of the early pioneers in technology and computer science were women. Grace Hopper (development of COBOL) and Adele Goldstine (wrote the first programs for the ENIAC computer) in the 1940s.

Adolescent males are more likely to "tinker" with computers in higher numbers (Mims-Word, 2012). Males are generally more inclined to utilize technology to explore and discover as a norm, with this engagement being introduced by a parent to develop an interest in technology.

Females appear to view technology in a transactional sense. In AAUW's research, it is interesting to note that adolescent females view technology as a tool as an extension of themselves while males (Anonymous, 2000). This insight may explain the lack of engagement for many females in relation to technology as a career. For example, they may use a car as a means of efficient transportation. However, they have no interest to explore or understand how the vehicle works beyond turning the ignition.

The dramatic difference in the female ratio is perplexing when considering earning potential. Since 1970, the median earnings of female information technology professionals are 80% more than all occupations (Beckhusen & Bureau, 2016). It is interesting to note that the position with the highest percentage of females is database administrators, a position that requires additional technical skills.

Therefore, with ample job availability and higher earning potential, the lack of female representation for roles in an information technology career are discouraging.

Attitudes and Perceptions of Students

In the last two decades, a great deal of research has been completed on the lack of interest in students choosing a career in the sciences. While there is a great deal of attention, popularity and adoption of technology, the attitudes toward a career in technology still lag. Some research suggests that student experiences relating to technology and sciences at school shape their perceptions (de Vries, 2005; Osborne & Collins, 2000; Stein & McRobbie, 1997). Research by Lindahl (2007) confirms that any interest in science or technology careers are generally determined by the age of 14.

Research by Ardies et al. (2015) found that as males transitioned into the second year of their secondary education their technology interest developed. Females regard technology as more of a masculine subject. Their findings also suggest that the gender bias develops a more distinctive difference.

Even after 44 years, the research of Coser (1974) relating to workplace issues is more popular than ever. As Coser identified the family and workplace as greedy institutions, the work-life balance issue has become a focus of discussion within business organizations and employees. Some research suggest that work policies are perceived to be less flexible in STEM careers. Specifically, engineering firms do not simplify the life balance issue enough, causing women to leave STEM careers (Gill, Sharp, Mills, & Franzway, 2008; McIlwee & Robinson, 1992). Students who define family flexibility as a factor when choosing their major are less likely to select STEM majors (Valentino, Moller, Stearns, & Mickelson, 2015).

Influencing Characteristics and Factors

A broad definition of perceived or subjective norm is "the perceived social pressure to perform or not to perform the behavior" in question (Ajzen, 1991). Finlay et al (1999) further describe a subjective norm can also be defined as an individual's perception or "opinion about what important others believe the individual should do". Students' choices can be prompted to perform behavior based on the influence of others.

In order to accomplish the research objective, it is important to determine the subjective norms, perceptions and thoughts that could influence selecting information technology as an undergraduate major. Therefore, an analysis of research was completed to gather the various constructs. The analysis resulted in twelve constructs as the foundation for the development of a survey instrument. The constructs and the related research citations are compiled in Table 2.

Construct	Research Citations
Aptitude to study information technology	(Joshi & Kuhn, 2011; Kuechler, McLeod, & Simkin, 2009; Walstrom, Schambach, Jones, & Crampton, 2008)
Interesting to use; Complete work with technology	(Heinze & Hu, 2009; Kuechler et al., 2009; Walstrom et al., 2008)
Difficulty of major; Requiring significant study time	(Kuechler et al., 2009; Walstrom et al., 2008)
Interest in information technology	(Joshi & Kuhn, 2011)
Availability of job positions	(Heinze & Hu, 2009; Joshi & Kuhn, 2011; Kuechler et al., 2009; Walstrom et al., 2008)
Gaining a high starting salary	(Joshi & Kuhn, 2011; Kuechler et al., 2009; Walstrom et al., 2008)
Influence of media	(Walstrom et al., 2008)
Importance of self-image; Image of information technology professionals	(Fox, Hindi, & Remington, 2001; Joshi & Kuhn, 2011; Kuechler et al., 2009; Walstrom et al., 2008)
Social image; considered a respectable career	(Joshi & Kuhn, 2011; Kuechler et al., 2009; Walstrom et al., 2008)

Intent to major	

Table 2 – Research Constructs and Related Literature Review

RESEARCH METHODOLOGY

Survey Instrument

The survey instrument was compiled using two sources: 1) questions designed directly from past research studies and 2) designing questions to gather the students' accurate perceptions for the additional constructs.

To complete this research study, 37 questions were compiled to gain the insights and perceptions, including a question on the respondent's gender. The order of the questions in the survey was arranged so that the redundant (reworded) construct questions were not placed in sequence. The survey was pilot tested with both students and faculty in order to identify grammar and ambiguous wording. The pre-test feedback was analyzed and applied to compile the final version of the survey instrument. The survey was coded into an online survey tool (Qualtrics) to administer efficiently and eliminate response data entry.

The listing of constructs and associated number of questions are compiled in Table 3. Each of the questions were measured on a seven point Likert scale. The scale for each question is defined in the fourth column as Strongly Agree vs. Strongly Disagree (SA/SD) and Extremely Important vs. Not Important At All (EI/NI). In each scale, the value of one (1) is identified with the first scale (strongly agree or extremely important). In the discussion section, using the adjective "lower" is defined as a higher responses score, but lower toward the more negative scale (strongly disagree, not important at all).

Construct Category	Construct Name	Number of Questions	Question Scale
AP	Aptitude	2	SA/SD
AT	Attitude	2	SA/SD
DM	Difficulty of Major	2	SA/SD
IN	Interest in IT	5	SA/SD
JA	Job Availability	2	SA/SD
JS	Job Salary	2	SA/SD

WE	Workload Environment	5	SA/SD
IM	Intent to Major in IT	2	SA/SD
	Gender	1	SA/SD
	Total	***37***	

Table 3 – Survey Construct Summary

Survey Population

First-year undergraduate students were selected as the population for this research study. Many undergraduate students have not declared their major. A study estimated the number of "undecided" students between 20 and 50 percent (Gordon, 2007). The scope of this research is to compile the perceptions for entering college students; as they begin their higher education experience and exploration.

Students registered in the first-year survey course in business were asked to complete the survey.

Hypotheses

Twelve hypotheses were compiled based on the perceptional constructs as well as the intention to declare information technology as a major. The hypotheses are listed in Table 4.

Hypothesis	Description
	There are no significant differences between gender based on the respondents …
H1	… aptitude in information technology.
H2	… attitude to gain a career in information technology.
H3	… perception of the difficulty to major in information technology.
H4	… interest in information technology.
H5	… believe that there are sufficient information technology positions available.
H6	… believe that salaries for information technology positions are high.
H7	… are influenced by various media environments.
H8	… have a positive personal image of information technology professionals.
H9	… have a positive social image of information technology professionals.
H10	… are positively influenced by others relating to information technology careers.
H11	… believe that a career in information technology has a positive work environment.
H12	… believe that they will intend to declare information technology as a major.

Table 4 – Research Hypotheses

Each of the eleven hypotheses will be evaluated using the responses of the students' survey completion. The evaluation will be completed by analyzing the response data through an analysis of variance (ANOVA). This statistical technique will measure the variation among and between groups of a population to determine any differences among group means.

In this research, gender will be used as the categorical variable to analyze each of the eleven hypotheses. The completion of the analysis will determine if differences, if any, exist by gender.

FINDINGS AND RESULTS

Survey Response

Three deployments of the survey were administered in the three semesters between Fall 2016 and Fall 2017. Over the three survey periods, 541 students completed the entire survey. Seven completed surveys responded to the gender question as the third item (no response) were omitted from the analysis. With the number of respondents for the analysis (534), the majority of respondents were male (63 vs. 37 percent). The institution's current male-to-female ratio (62 vs. 38 percent) of the entire first-year class accurately represents the survey response frequency distribution.

A summary of the survey response frequencies is shown in Table 5.

Semester	Male	Female	Total
Fall 2016	110	53	163
Spring 2017	131	68	199
Fall 2017	96	76	172
Total	337	197	534
Percent	63.1%	36.9%	100%

Table 5 – Survey Response Summary

Analysis of Variance Results

For each respondent, each of the individual questions associated with the construct was averaged. For example, the five media influence questions were averaged to compile an average score for the "MI" construct for all 534 responses.

The analysis of variance statistical tests were completed using SPSS. The ANOVA was completed by using the twelve construct average scores as the dependent list with the gender response as the factor.

The statistical results of the analysis of variance are compiled in Tables 6 and 7.

Construct	Gender	N	Mean
Aptitude	Male	337	4.32
	Female	197	5.15
	Total	534	4.63
Attitude	Male	337	2.90
	Female	197	3.57

Table 7 – ANOVA Frequencies and Means Results

Hypotheses Evaluation

The outcome of the ANOVA statistical analysis provided an evaluation of each dependent variable as it relates to the group factor (gender). The ANOVA results calculated the F-score, significance level and all means (group and grand).

Each of the p-values were evaluated based on the traditional ranges associated with previous research (p<.001, p<.01, p<.05). For the twelve hypotheses, seven were rejected for p-values calculated less than the accepted value (.05). Several of the research hypotheses (H1, H2, H3, H4, H12, and H14) were found to be highly significant (p<.001).

The results of the ANOVA statistical analysis found that there were highly significant differences between gender relating to aptitude, attitude, difficulty of major, subjective norms and intent to select information technology as a major. The remaining hypothesis (personal image) was found as significant in terms of differences between females and males.

The statistical results of the hypotheses evaluation is compiled in Table 8.

Hypothesis	**Construct**	Mean Grand	Mean Male	Mean Female	**Sig**.	
H1	Aptitude	4.63	4.32	5.15	p<.001	Reject
H2	Attitude	3.15	2.90	3.57	p<.001	Reject
H3	Difficulty of Major	3.52	3.35	3.85	p<.001	Reject
H4	Interest in IT	3.01	2.80	3.36	p<.001	Reject
H5	Job Availability	3.11	3.06	3.19	ns	Accept
H6	Job Salary	3.04	3.00	3.11	ns	Accept
H7	Media Influence	3.50	3.65	3.51	ns	Accept
H8	Personal Image	5.50	5.39	5.69	p<.01	Reject
H9	Social Image	4.13	4.12	4.16	ns	Accept
H10	Subjective Norm	4.82	4.67	5.09	p<.001	Reject

H12	Intent to Major in IT	5.48	5.30	5.79	p<.001	Reject

Table 8 – Result of Hypotheses Testing and Evaluation

DISCUSSION AND CONCLUSIONS

Discussion

Even after decades of discussions, innovative teaching techniques, targeted promotions of STEM-based careers/majors, the perceptions (and probably reality) between females and males relating to information technology careers still remains distinctive. More than half of the hypotheses calculated significant differences between genders.

Aptitude: The results of the respondents clearly indicate that females do not consider their fit and performance as lower as their male peer group. The difference between the mean values (0.83) is not only highly significant, but also the lowest of all hypotheses constructs. The mean scores indicate that their visualization in an information technology position is much less positive than that of males; somewhat disagreeing with the question statements.

Attitude: The questions associated with this construct explored whether they believed that the use of information technology at work would be interesting. Coincidently, the attitude toward the technology use is also lower. While the differences between the gender means is lower than aptitude (.67), it remains very high. On a positive note, the range between the mean scores of attitude and aptitude increased more toward strongly agree. Although, the percentage decrease in the gender averages decreased more for males (49%) than females (44%). The differences remain significantly significant.

Interest in IT: In terms of the interesting in information technology and business, females indicate that their interest is lower than males. Male students scored the highest inclination toward interest in IT than any other construct composite; 19% higher average than females. The question probes the interesting in working in information technology, using software as well as working in a team, analyzing/presenting business problems. After reviewing the question, the responses may need to be separated for further analysis.

Difficulty of Major: One of the questions associated with this construct was written with a negative version of the other question. Therefore, to maintain accuracy of the statistical analysis, the data was recoded to the scale of the other question prior to the completion of the ANOVA computations. Anecdotally, the difficulty of STEM-based majors appears to a significant influence on the selection of those majors. Ironically, the mean scores (both overall and major) were lower than expected; trending between 3.35 (males) and 3.85 (females). The final mean values (grand and gender) are higher than the aptitude mean responses. The results indicate that even though the perception of their ability in information technology is lower they do not believe the major's difficulty is as negative.

Intent to Major in IT: Obviously, this construct is important as a reflection of their overall thoughts on an information technology major. Each of the mean scores are very low as compared to the other construct scores (the personal image construct averages) are very similar. However, while pointing to a very negative inclination to major in technology, the difference between the gender scores is the narrow than four other scores (aptitude, attitude, difficulty and interest); representing 9.2% difference in the mean scores. Still, it reflects an extremely pessimistic view of information technology careers (between somewhat disagree to disagree).

Subjective Norms: The influence from people on the student was found to be highly significant between genders. The difference in the gender mean scores was 9.2%; the same as the intent to major construct.

Personal Image: The perceived personal image of information technology professionals is considered "nerdish", anti-social and boring. Both questions were posed by suggesting words using the three words noted above; tending to focus on the negative words. The mean scores associated with this construct (grand and gender) are the lowest in the construct averages. However, based on the negative construct, the averages indicate between somewhat disagree to disagree. When considering these results, it is interesting that students are not as negative about the perceived personal image of technology professionals. Coincidentally, female students are lower than males, although by the smallest percentage difference (5.5%) and significant ($p<.01$).

Each of the remaining five constructs calculated no significant differences between males and females. This result would indicate that males and females think and act in a similar manner relating to the availability of jobs, high salaries, media influence, social image and workload environment.

Job Availability: Students are, for good reason, concerned embark on a career that have positions available upon completion of an undergraduate degree. The number of technology positions will be ample to find a positon and to maintain a successful career.

Job Salaries: The results associated with job salaries (high and satisfying) are very similar to the job availability results.

Media Influence: The current generation is affected by media; especially social media. Students were asked to provide the influence of five media experiences (career fairs, newspapers/magazines, job listings, social media and television/movies). There was no significant differences between males and females. The highest individual means were calculated (respectively) as 2.93, 4.04, 3.07, 3.82 and 4.12. The most influential are career fairs and job listings. The opposite end of the range averages indicate that social media, movies and newspapers are not ad influential as the other forms.

Social Image: The social image associated with information technology leading to a respectable career do not indicate any significant differences between males and females.

Workload Environment: The students were asked about the level of challenge and ability to obtain a leadership position in a business. It is clear that students (both male and female) have not been influenced in a negative manner by the workload associated with technology positions.

Conclusions

The results of this research are not surprising. Males and females have very delineated perceptions and thoughts about technology careers. Some interesting thoughts and insights are as follows:

- Both males and females believe that their use of technology is important. This perception may be the level of integration and use of technology in their daily lives as students and individuals. What is interesting is that level of technology use does not equate to the level of aptitude with technology. This disconnect may be due to their view of technology as an appliance and not a tool to gain market-based, functional skills to apply in their job. It is also possible that they believe they cannot develop those skills successfully.
- Ultimately, the results of this study clearly indicate that males are more influenced by professors, friends, peers and advisors than their female peers are. Does this result indicate that males more inclined to seek out advice? Or develop more relationships that gain advice organically?
- While both genders somewhat agree that the availability of jobs is suitable to start a career, there is a reasonable disconnect is present relating to the number of jobs actually available and high starting salaries. It is unfortunate that the discussion, in the

household between parents and college-age children, on gaining an entry-level position with high salary is not framed to include technology positions.

- Students do not seem to be affected significantly by the social image as much as the personal image associated with technology positions. This outcome would suggest that the perceptions, whether positive or negative, ascribed by others is not as important as their own personal image of a career selection. Anecdotally, this result may be specific to generational characteristic of self-absorption; that their personal image (at least for career) is more important in how they are perceived by society in general.

Other influences and perceptions may be permeating through the thoughts of young people. Do technology positions appear to be very compartmentalized within the information technology department/division? With no other contact outside of their career positions? Sales people meet with customers on a frequent basis. Marketing personnel promote products by collaborating with internal personnel (sales representatives, brand managers, etc.) and external resources (graphic designers, photographers, writers, research analysts). From the students' perspective, they may view technology positions as isolated and only collaborating in a small circle of positions and functions within a business.

Does that mean that students consider technology careers as too corporate? Too hierarchical? Too isolated from the business organization? Or that technology does not have the opportunity to collaborate with and present to management and organizational leaders?

In addition, students may believe that technology personnel cannot navigate and transition to other careers. Do students believe that the skills, experience and projects do not translate to other positions and careers? If so, students may believe that technology professionals are "pigeon holed" and remain as a technology professional for their entire career.

Limitations and Further Research

When completing this pilot study on the survey data, several issues were uncovered.

The results reveal a potential disconnect between aptitude and use of technology was fascinating. It would be interesting to probe further to separate and define what information technology students use and what technology they would utilize as an IT professional.

The other disconnect between the results and reality relate to the need for high-paying, available jobs and technology. With all the discussion of the high-cost of higher education and the ability to repay student loans, the entry level salaries and positions available should be able to "catch the eye" of students. For example, students selecting accounting as a major clearly know the starting salaries and jobs available upon graduation. No one is suggesting that a student enter a major or career they do not enjoy. However, it may be possible that students refrain from an open and objective exploration relating to technology based on the associated perceived negatives.

Future statistical analyses should be completed to develop potential correlation on the various influences and perceptions of students and the intent to major. It would be interesting to determine whether any specific constructs are more dominant over the intent to major in technology over other constructs.

From the results of this study, it is clear that there are clear and distinguishable differences between males and females. The endless discussion of the number of females entering technology positions (and STEM-based careers in general) remain important and requiring attention. Education leaders (from K-12 to higher education) as well as business leaders need to continue promoting, acting as role models and active advocates with young people. The increasing thirst for technology by businesses and individuals reflects the need to continue all efforts to promote technology as a formable and satisfying career. Our ability as a national economy will specifically depend on a) increasing the number of young people who desire a technology position and b) not allowing the trend to decrease.

ABSTRACT

This paper reports on incremental findings from our investigation into rationales for sustainability practices. Three theory strands; resource-based view (RBV), stakeholder and relational corporate social responsibility (RCSR) theories are advanced to develop a conceptual model for logistics and transport sustainability. Qualitative methods are employed to collect and analyze data from 18 organizations in Sweden and Nigeria over a 2-year period, conducting 37 semi-structured interviews with management executives. Preliminary findings support the tri-combination framework as adequate for understanding sustainability practices by organizations, highlighting size and context as potentially moderating factors in the decision-making process. Findings offer incremental insights that enhance understanding of how logistics and transport organizations evolve practices to support their commitment to sustainability.

KEYWORDS: Sustainability Commitment; RBV; Relational CSR; Stakeholder Theory; Freight Transport

Research remains inconclusive about the role and responsibility of organizations within society. The common narrative presents the firm as a competitive unit with a primary objective of profiting (Freidman, 1962, Barney, 1991). However, recent studies have acknowledged internal and external factors that are impacting organizations towards other goals besides wealth creation (Aguilera et al., 2007; Palsson and Kovac, 2014). With these exerting pressures on organizations, the focus is on management for leadership, responsibility and accountability in terms of strategic directions for their organization. Managing for sustainability is thus a critical component of strategic management, requiring advanced stratagems for operating in different

climes across the world (Logsdon and Wood, 2002; Aguilera et al., 2007; Tob-Ogu et al., 2017). We note the importance of academic discourse and recognize the validity of the plethora of management theories that have provided useful and relevant guidance on firm strategies at meso, macro and supra levels; yet, recent scandals involving multinational and local organizations like Rolls Royce (Brazil) and Zara (Turkey) to mention a few, create uncertainties about the commitment of organizations to a sustainable future, with the British International Freight Association suggesting a 7% increase in whistle blowing within the logistics and transport sector (BIFA, 2018). We view commitment as tied to an understanding of the 'relationship' between organizations and society, where this understanding influences the decisions of management and the inviolability of the commitments on sustainability. To improve our understanding of the decision process that drives managerial decisions and actions in this regard, the following research question is posed; "Can management theory integration improve understanding of sustainable decision making by management in the logistics and freight transport sector?" In this paper, we review three prominent strategies/theories and advance a framework that unifies elements from different theories into a single perspective to examine the 'necessary' firm and society relationship framework to improve sustainability performance. The rest of this paper is structured accordingly: section two presents a review of the literature on sustainability; in section three, we review relevant theories; our research methodology is detailed in section four; whilst sections five and six see presentations of our results and conclusions respectively.

LITERATURE REVIEW

SUSTAINABILITY

Sustainability is a multi-faceted construct with a variety of conceptions centered on the idea of a better world (Gladwin et al., 1995; Behrends et al., 2008). In this study, the term is used to capture the tri-dimensional concept of sustainable development as protecting the opportunity for future generations to meet their needs by catering to people, planet and profits as an inclusive package (World Commission on Economic Development; 1987; Elkington, 1998). It thus represents activities, practices and impacts for creating positive societies and business outcomes within livable environs. Gladwin et al., (1995) advocated the acceptance of both objective and subjective values in assigning meaning to the concept, suggesting that clarity would improve over time as we developed consensus on characteristics, operational indicators and moral injunctions. They advance connectivity, equity, inclusiveness and prudence as principal components of viable sustainability definitions.

Accordingly, we recognize the validity of bespoke indicators and variations that are perhaps underlined by specific environmental pressures within specific firm contexts. However, sustainability initiatives and practices should at least aim to promote wholesome economic efficiencies, positive social impact and environmental preservation outcomes that improve the in-situ experience of the society where organizations exist or operate in (WCED, 1987). Economic efficiencies refer to the optimal allocation and use of resources to generate profit or output, positive social impact underlines the effect on individual feelings, thoughts or behaviors from the actions of others (Latane, 1981) and environmental preservation encompasses policies and practices that address concerns relating to climate change, wildlife welfare and ecological balance. It is permissible that adherence to these principles will enhance the attainment of the WCED (1987) construct on sustainability.

Despite the recognition of contextual pressures as potentially limited, for the typical logistics firm, contexts have both spatial and geographic implications stemming from globalization and information and communications technology (ICT) pervasion. This is true, even for most non-multinationals as increasing trade and globalization is leading to further interdependence

between organizations through a hydra-triadic web of relationships. Our remit precludes the debate on the universal conceptualizations of sustainability, however the preceding supports the foundation for examining the integration of sustainability practices into firm strategies, otherwise referred to as sustainability commitment in the paper.

SUSTAINABILITY COMMITMENT

A survey of 2045 professionals reported apathetical engagements between organizations and the United Nations Sustainable Development Goals (SDG) in 2016, with planned engagement by organizations at less than 50% (Ethical Corporation, 2016). Similar scandals relating to low pay and labor exploitation (Zara), gender inequality (BBC), environmental contamination (Shell Nigeria) and child labor (Apple, Marks & Spencer) raise questions about the commitment of organizations to sustainability (Guardian, 2014; Amnesty International, 2016; BBC, 2016). This unwholesome commitment to sustainability has engineered the term 'greenwashing' which represents the creativity of some organizations in managing their sustainability portfolio through a range of deflection strategies (Werbech, 2009; Laufer, 2003). As independent scrutiny increases, the onus falls on management to evolve, disseminate and enforce sustainability initiatives within their operations and supply chains. However, the common tendency seems to focus on evolving and dissemination as opposed to enforcement. As captured by Werbech, (2009) leading global organizations seem more focused on communicating green efforts as opposed to improving their practices. This practice is perhaps buoyed by the increasing availability of data to support competitive advantage through sustainable practices. There are a number of challenges that arise with this approach:

Accessibility: Information accessibility is at its highest level in the history of mankind, driven by advancements in ICT. Not only has accessibility improved, the capacity to disseminate to the largest audiences within the shortest possible time is immense. Organizations will eventually be like gladiators, whose fate will be decided by society based on observations in real time Coliseums.

Competency: Perfection through practice principles will apply. Organizations will probably develop superior competency in communicating sustainability efforts as opposed to competencies in sustainability practices. In the long term, they will lose any competitive advantage that arises from the implementation and improvement of sustainability practices as opposed to communication. Impairment: Ignoring the problem does not always address the problem. By relying on evidence that sustainability can support competitiveness, there is an implicit acceptance that sustainable practices offer value to customers and society at large. Greenwashing counteracts acquiescence of sustainable value streams with potentially dire consequences for future competitiveness.

Importantly, the literature is relatively limited on why organizations pursue non-sustainability strategies or green wash (Werbech, 2009, Palsson and Kovac, 2014). Millar et al., (2012) argue that despite global acceptance of sustainability, there is still a dearth of management models that support integration into business practices. This perhaps explains the antecedent of greenwashing by organizations and highlights gaps on sustainability integration within the literature.

Accordingly, we emphasize links between management knowledge and sustainable practices, where knowledge impacts practices. Importantly, the literature recognizes links between theory, strategy and practices (Anderson and Paine, 1975). For example, Sutcliffe (1994) established theory as promoting our understanding of links between firm practices and environmental inputs. Also progressing on Anderson and Paine's (1975) work, Beyer et al., (1997) went on to establish links between environments and management strategies, highlighting the role of perceptual factors (information) on businesses. Information assumes critical influence and it is plausible that managements' quasi-commitment to sustainability may stem from information

perceptions about their environments rightly or otherwise (Massis et al., 2013; Ozleblebici et al., 2015).
This link between theory and strategy can be multi-directional, i.e. we can explain business strategies through theory and we can evolve business strategies through theory. In the case of the latter, the outcomes engineer strategic innovation that supports management activities. In this study, we adopt a reflexive strategy to develop and review a framework for theorizing on firm's approaches to sustainability. Recognizing the epistemological limitations, our model offers adopting managers an innovative platform for evolving sustainable strategies that focus on recognizing, accepting and improving their sustainability practices.

THEORETICAL MODEL

Despite the progress and proliferation of management theories to support understanding, there are still significant gaps or limitations with individual theories. As a developing concept, theoretical explanations for sustainability practices fail to provide comprehensive understanding of why management decide and act to be sustainable. More often than not, theories are skewed towards one of the three pillars and this creates knowledge silos and limits our current understanding. To tackle this phenomenon, Mayer and Sparrowe (2013), accentuate the relevance of theory combination to management research, establishing four scenarios that justify the integration of theories in research:

I. Single Phenomenon - two theoretical perspectives: common dependent variable that allows for investigation from two vantage points. E.g. RBV and TCE on subcontracting.
II. One Phenomenon with two seemingly disparate theoretical perspectives – Identifying and employing seemingly conflicting theories to complement understanding of phenomena.
III. Adaptation – Applying one theory to the domain of another theory – E.g. Social theory and TCE to explore social relationships outside organizations or government behavior.
IV. Combining multiple streams of research sharing similar explanatory accounts – More than two different theory explanations are fused in dialogical contexts to integrate their explanations under one broad umbrella.

Palsson and Kovacs (2018) recognize the limitation and appropriate stakeholder and RBV theories to evaluate practices in transport. Whilst their study offered useful insight into the internal and external drivers of green practices by transport firms, it also validated the limitations of single theoretical lenses. Despite the usefulness of their findings, their sample did not reflect the diversity that is present in today's logistics and freight transport environment. Since we know that the complexities of sustainability and potentially conflicting firm epistemologies support theory integration frameworks that promote understanding. In this instance, we sought to build on their study by combining the resource-based view, stakeholder and relational corporate social responsibility theories to develop a suitable model for theorizing sustainability in logistics and freight transport. Such insights offer useful understanding of management decision influences and can help improve interventions.

Resource Based View: (RBV)

Barney (1991) is widely regarded and cited as the pivotal work in the emergence of RBV. In the foundational text, "Firm Resources and Sustained Competitive Advantage" Barney was reacting to the dominant positioning school of the 1980s, which focused managerial attention to external considerations, industrial structure for example.

In contrast, as illustrated by Hoskisson et al., (1999), RBV direct firm's attention towards internal resources in an effort to identity assets, capabilities, competencies and forms of coordination with the potential to deliver sustainable competitive advantage (Liu et al., 2010; Grant, 1991 Wernerfelt, 1995). The essence of RBV is captured in the notion that the differences in organizations' resource endowment result in differences in firm performance. Therefore, a key insight arising from the RBV approach is that organizations are made up of heterogeneous resources with varying importance and potential configurations; therefore, managerial effort must be dedicated to identifying core competencies though specific value-creating strategies (and causal relationships) for sustainable competitive advantages (Eisenhardt and Martin, 2000; Barney, 1991).

Furthermore, the "VRIN" framework popularized by Barney (1991) is the commonly accepted standard within the RBV as providing the basis for understanding resources that can be sources of sustainable competitive advantage. VRIN is an acronym for value, rare, inimitable and non-substitutability. 'Value' denotes the extent to which the combinations of a firm's resources match the external environment and enables it to exploit the business environment advantageously (Hoskisson et al., 1999; Barney, 1991). 'Rare' captures the perceived inaccessibility of a firm's resources in the market it competes in; 'inimitability' represents the difficulty of imitation without higher cost disadvantage and 'substitutability' addresses the availability of similar resources that are available to other organizations. Underlying the VRIN framework, that strategically valuable resources must be scarce, inimitability and non- substitutability (Barney, 1991; Bromley 2009), is the view of factor market as imperfect. But divided into the tangibles and the intangibles, several researchers have argued that intangible factors are likely to satisfy Barney's VRIN criterion (Johnsen et al., 2014).

Pertaining to the objectives of this study, RBV theories have been applied in studying responsibility of organizations to society and people that live in it (Litz 1996; Aragón-Correa and Sharma 2003; Colbert 2004; Sirmon et al., 2007). For example, Litz (1996) argued for recognizing that social and environmental dimension of organizations' activities could be sources of strategic advantage. Likewise, Sirmon et al., (2007) argued that environmental factors can affect organizations' strategic resources. One shortcoming of RBV approach in this regard is the 'direct' internal and short-term nature of its analytical language (Sanchez, 2008). In essence, various researchers (Porter 1991; Sanchez 2008; Prime and Butler's 2001) have shown that RBV suffers from both conceptual and practical deficiencies. Some of the conceptual deficiencies include the failure to provide an adequate conceptual basis for identifying resources that are strategically valuable to a firm in a given competitive environment, and the absence of chain causality in its language (Sanchez, 2008; Heene and Sanchez, 2018; Becerra 2009). Borrowing from the work of Stinchcombe (2000) and Johnsen et al., (2014), some practical deficiencies include the failure to supply critical investigation of how key capabilities are acquired; it also provides little guidance on how to develop resources to meet the set criteria.

Consistent with the objective of this study, the systemic nature of organizational capabilities and the "contingent" nature of resources establish the limitations of RBV as a single theoretical lens, because it views resources in isolation to the web of interactions that combined to produce them. Theories that seek to understand the edges of firm activities will increase the robustness of RBV and provide a complete language for the research phenomena of interest. We have selected stakeholder approach to perform this function: stakeholder suggests that organizations should formulate and implement processes with different stakeholders in mind.

Stakeholder theory

The essence of the stakeholder approach is captured in the notion that (1) shareholders are not the only party affected by the activities of organizations, and (2) the other parties (or

stakeholders) should be considered in firm management strategies. Robert Freeman (1983; 1984) is extensively regarded and cited as providing the basic analytical and conceptual framework on which stakeholder theory is based. In its original rendering stakeholders were defined as "those groups without whose support the organization would cease to exist" (Freemen 1984). Although this definition has undergone several refinements (see Friedman and Miles 2006), the basic idea persists. Alkhafaji (1989) developed the concept of dynamic stakeholders, arguing that the mix of stakeholders may change over time; nevertheless, there are some basic stakeholders like customers, employees, suppliers, communities, governmental bodies, political trade associations and trade unions.

For Freeman (1984; 2010), there are three level of analysis that must be consistent if the stakeholder concept is to make a difference in the way organizations are managed: the rational, the process and the transaction levels. At the rational level, an understanding of who are the stakeholders and the nature of their stake is necessary (Elias and Cavana, 2000). This does require an extensive research to understand the nature and the source of the interest of stakeholders. Freeman (1984) employed a generic stakeholder map for a starting point, but it is also possible to prepare stakeholder map based around a strategic issue. At the process level, it is necessary to understand how the organization implicitly or explicitly manages its relationships with its stakeholders, and whether this fits with the rational stakeholder map as well as the expectation of stakeholder (Freeman 1984; Deverka et al., 2012). Finally, the transaction level seeks to understand the set of transactions and negotiations between organization and stakeholders to determine whether these negotiations fit with the stakeholder map and the organizational processes (Elias and Cavana 2000; Carroll and Buchholtz 2012). Successful transactions with stakeholders are built on understanding the legitimacy of the stakeholder and having processes to routinely surface their concerns.

In relation to the current study, stakeholder theory as a firm-level intervention instrument may be relevant based on layers of complex interactions that usually conspire to provide the context of firm and resources. However, whilst stakeholder theory has enhanced management studies on sustainability and organizational practices, it has also attracted considerable criticisms (Nankervis et al., 2005; Weiss, 2004; Mansell 2013). Most importantly, a big limitation is the absence of time scales for managing stakeholder expectations as well as optimal decision making for simultaneously satisfying competing stakeholder interests, where they have similar power and interest on or within the corporation. In practice, organizations often end up serving the material interest of powerful groups in communities as copious examples from the developing world bears out. Additionally, stakeholder-mapping inaccuracies may often reflect and result in counter-productive outcomes for organizations and these further limits the unilateral application of stakeholder theory to drive sustainability strategies by management.

Corporate Social Responsibility (CSR)

At its core, CSR perspectives integrate the concept of responsibilities as well as discretion into a form of self-regulatory mechanism whereby businesses observe ethical standards as well as norms. Matten and Moon (2008) argues that CSR should reflect social imperatives and consequences of business success, articulating responsibility practices and policies as preferred by the corporation. This pro-organization focus highlights potential weaknesses of some CSR interpretations, which unlike stakeholder theories, fails to consistently integrate the perception or advice of specific groups (McWilliams and Seigel, 2000).

Authors like Garriga and Mele (2004) had classified CSR theories into four categories: instrumental, ethical, integrative and political, albeit with latent classifications. According to them, the instrumental theorists follow the traditional philosophy of organizations as an instrument of wealth creation and no more, the ethical theorists are at the other extreme with normative stakeholder principles, universal rights empowerment and sustainable development

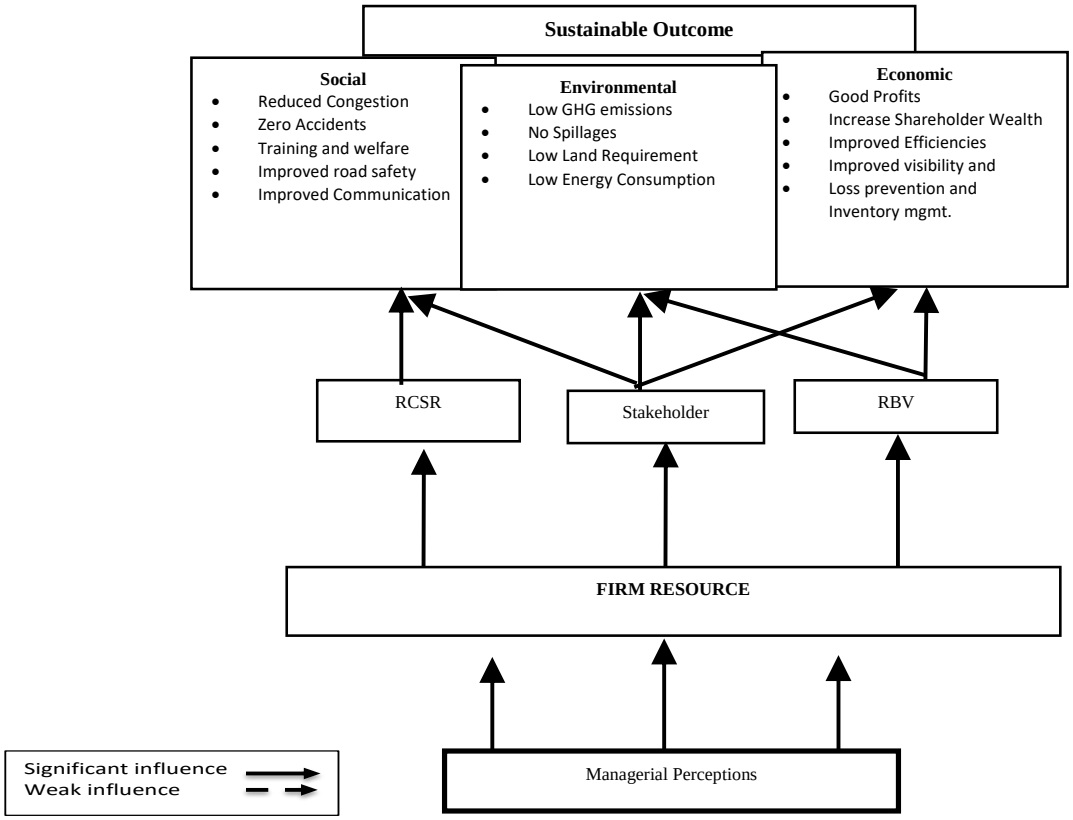
at the core of their constructs. The political and integrative theorists are compromises that fall between the extremes, acknowledging social responsibilities that confer management with social power (political theories). They also acknowledge the requirement of organizations to respond to social issues within their environment; integrative theories on corporate social performance (Carroll, 1979), public responsibility and stakeholder management (Emshoff and Freeman, 1984). Seechi (2007) condenses this framework into a more contemporary framework with three categories; the utilitarian, managerial and relational.

The utilitarian theorists re-echo the instrumental classification, emphasizing the role of organizations as an economic tool with no explicit social responsibility besides those that are functional or cost imposing on organizations (Coase, 1988; Friedman, 1970). The managerial theorists represent the compromise school where although avoiding the extremes of Friedman's postulation, they justify organizational philanthropy only if they will yield some economic benefit, tangible or intangible (Drucker, 1973). Effectively, this set of integrators began to drive studies around competitive advantage as a basis for CSR practices and this perhaps may be credited with the biggest acceptance of CSR theories within strategic management research at the time (Vogel, 2006). Finally, the relational school of thought conceptualizes CSR as emanating from the 'citizenship' construct with implicative benefits and responsibilities. It ties the corporations to the social contract theory where the operative cost-benefit scenario applies to the relationships with taxation being just one of many costs to organizations (Seechi, 2007; Woods and Logsdon, 2002).

The relational (RCSR) theory is adopted in this study as it offers the greatest departure from the traditional competitive theories. Our aim is to reflect and integrate reasonable differences in order to update management knowledge for sustainability strategies. According to Habisch et al., (2005), the discussion about CSR is very heterogeneous because stakeholders (consumers for example) have different conceptions of what makes a firm socially responsible: environmental standards, providing social amenities etc. Likewise, the approaches are also context-specific: corporate philanthropy, integrating social movement (like fair trade) etc. In this regard, CSR theories have been used for studying responsibility of organizations to specific societies (Carroll 1989; McGuire et al., 1998; Burke and Logsdon 1996; Ite 2004; Orlitzky et al 2003; Matten and Moon, 2008).

As previously highlighted, our conceptualization is that organizations seek a balance between social, environmental and economic viability in their quest to be sustainable (Palsson and Kovacs, 2014). This creates complexity challenges for management in decisions on sustainability and the extent of their commitment. These complexities also have implications for theory modeling to support our understanding of managerial decision-making processes when it comes to sustainable practices (Figure 1).

Figure 1. Conceptual Framework – Integrating Theories



To integrate these theories, we examined the literature to identify some key indicators across the triple bottom line categories; social, economic and environmental factors within the transport and logistics sector. The literature was then used to inform hypothetical links between different theories and some of the factors identified. For example, profits, efficiencies and energy consumption links had been identified by previous studies (Palsson and Kovacs; 2014). In some instances, there were no existing studies that had empirically tested some indicators or offered theoretical insight and we therefore apportioned indicators based on heuristic hypothesis of the indicator as relates to the constructs of the theory. For instance, although non-organizational training and welfare (Figure 1) had not been investigated with respect to theory, we examined this as a function of corporate social responsibility and thus established links. At this conceptual level, our goal was to provide links and there was no empirical evidence to support the strength of the connections between different theory nodes and the sustainability categories.

By combining these three leading theories into a single framework, it is perhaps plausible to get a better picture of managerial decision frameworks that can support theory evaluation across different contexts. For example, although convenient for exploring sustainability, RCSR does not directly integrate perceptions of selected individuals representing specific groups but assumes responsibility on the basis of known duty (McWilliams 2000). Branco and Rodrigues (2007) describe the stakeholder perspective of CSR as the set of views of corporate duty held by all groups with a relationship to the firm. Both theories are not adequate for explaining 'social performance' as a factor for sustainable competitive advantage, and thus they are complemented by the competitive focus of RBV (RBV alone fails to consider factors surrounding resources). Societal wellbeing in this sense is crucial for sustainable or long-term competitive

advantage of firm given the reliance of resources on surrounding factors. Integrating these three theories into a framework can allow for the positioning of different factors and a broader theory scope for understanding management decisions regarding sustainability practices to achieve economic efficiency, positive social impact and promote environmental preservation in their practices.

METHODOLOGY

To test our decision model, we identified high impact developing and developed country (Nigeria, Sweden) sectors and adopted a multiple case study strategy to collect data using purpose and snowballing techniques to capture industry polar types (Voss et al., 2002; Yin, 2003; Eisenhardt and Graebner, 2007; Jugdev and LaFramboise, 2010). This supported our emergent studies and promoted theoretical appropriation by capturing the heterogeneous perspectives within the industry.

In the first instance, we identified Nigeria as an emerging country with significant freight transport operations albeit understudied. A few publications highlighting high reoccurrence of freight and logistics incidents with high human costs (fatalities) made the environment interesting. One of the research team members had access to several multinational operators in the sector and this further informed our decision to include Nigeria as one of our comparative environments for the study. In contrast, Sweden boasts some of the safest and leading sustainability initiatives in the area of freight transport. Previous collaboration with the City of Stockholm council offered knowledge of sustainable practices within the country. To aid validity, the research protocol had been developed and pilot tested with a selection of industry and academic respondents. The proposed work was also presented at one European conference with feedback helping to inform the final research protocol.

Following the identification of potential organizations and the validation of the research protocol (Yin, 2009), 37 semi-structured interviews and observations were conducted with management level executives in 18 organizations. We conducted the first phase of interviews in Nigeria in 2015 and the second phase of the study in Sweden in 2017. The sample consisted of middle and top management executives in the logistics and transport sectors (6 multinational organizations, 2 public institutions, six medium and 4 small organizations). Additional data collections have been scheduled for the mid and last quarter of 2018, with another 10 organizations identified for inclusion in our study. We hope to attain data saturation at the conclusion of the fourth phase of data collection.

In addition to the interviews, we employed in-situ observations and extensive documentary review to achieve data triangulation. By comparing different data streams, we improved the validity and reliability of our current findings.

Data analysis involved the use of the protocol supporting the development of coding frame to support analysis. Coding was implemented in three stages to extract, structure data and generate themes. In the first level, narratives from transcripts were extracted using NVivo11. Using the query function, implemented text querying and cluster analysis but checking the 1000 and 100 most frequent words from the data, and used the cluster function to map connections between words. Once the 1st 89 nodes or most reoccurring words with meaningful connection to other parts of the data were identified, we then supported the process with further content analysis and nodal grouping of the data. This led to a reduction to 26 nodes following second level structuring to group data using word-tree functions that highlighted patterns, relationships and usage contexts for the first set of nodes. 3 researchers independently developed codes from the 26 codes and agreed on defining scope for the themes. This led to an aggregation and resulted in 5 thematic nodes that represented the sustainability commitment rationales from the

data. The use of Nvivo11 and subsequent independent evaluation by different researchers improved the reliability of the data analysis process.
Finally, the emergent themes were compared with existing theory constructs, evaluating for similarities and differences with reference to the conceptual framework presented. The discussion below summarizes our findings on themes that inform the commitment decisions of management within the firms surveyed.

RESULTS AND DISCUSSION

As previously stated, we identified five main themes on sustainability commitment from the data; *competitiveness, palliation, innovation, security and duty*.

a) Competiveness: emphasized management willingness to pursue sustainability as means to competitive profiting. In this regard, economic consideration was regarded as primary drivers for practices. For example, 5 executives in Nigeria and Sweden were of the opinion that "sustainability offered the opportunity for gaining a high market share". This thinking was tied to compliance and communication of green practices in order to influence consumer perceptions and win market orders. Contrastingly, we found that multinational executives in Nigeria were more likely to emphasize this competitiveness theme compared to their counterparts in Sweden. The converse was true for small and medium enterprises in Sweden, who emphasized competitiveness compared to their Nigerian counterparts. There have been suggestions that business culture may influence 'reported' sustainability commitment in different climes (Guardian, 2016), however, this does not address the absence of uniformity on competitiveness amongst similar category of organizations in different climes. It is probable that many big organizations in different contexts face different competitive pressures and are more likely to focus meeting those challenges that in turn reflect the nature of the sustainability engagement or commitment.
b) Palliation: relates to practices that mitigate the impact of firm practices on society. We identified three strands to this: proactive, reactive and responsive.
   In terms of proactivity, we found that some organizations had robust evaluation frameworks that guided their activities, actively promoting practices that helped to reduce any impact of their operations on their immediate community. For example, one of the organizations in Sweden had a robust 15-year planning framework that not only accounted for their operations impact but actively incorporated the impact of other members of their supply chain into their accounting system. This led to practices like setting up a consolidation center to manage the flow of goods into residential areas, investment in low emission and low noise trucks as well as multimodal access to the consolidation center. This had no competitive connotations and was done because the management of the firm believed that it was the right thing to do.
   In Nigeria, our findings were more related to reactive and responsive measures. Perhaps the history of socio-environmental disputes affected the practices by organizations in this regard. Responsiveness relates to ready commitment to address impact concerns as they arise, whilst reactive practices were those that followed through after some disputes. For example, we found that some community concerns were only addressed after series of disputes between the organizations and the community concerned. In some cases, monies were paid out to community personnel, in other cases there were infrastructural investments to support compensation. Interestingly, we found little evidence to suggest that organizations in Nigeria desisted from specific practices simply because of the impact.
c) Innovation: closely linked to competitiveness, innovation offered organizations the opportunity to distinguish themselves. Not every firm linked competitive practices with

innovation and we considered this worthy as a stand-alone them. Typical examples from the data stem from the use of unconventional equipment to support reliability, e.g. use of mobile phones by small organizations in Nigeria to improve traceability of client deliveries, thereby reducing incidents of theft product diversion. In Sweden, organizations were actively involved in collaborative relationships that engineered innovative distribution practices like the combination of an urban consolidation center for both distribution and retrieval of raw materials. What was perhaps most intriguing being that the partnership involved a real estate firm, a major logistics firm and a waste management firm. This was an unusual partnership for logistics solutions, but it was effective and provided value to all concerned.

d) Security: encompassed the guarantee of continuity both in terms of safety but also access to resource. This was mostly an issue that arose from the Nigerian context. One executive reiterated:

"*We offer solutions and structure our processes in a way that it creates a sustainable business environment and also we function in a way that it wouldn't impact so much on our business network and the environment. Also, sustainability incorporates quality, security, safety and all that. Therefore, being able to carry out activities in a way that you can continue doing them without affecting the business*" – Managing Director H.

Consultative meetings and concessions, investment in infrastructure, location decisions and price decisions were some examples of security themed practices related to sustainability. Duty: perhaps philanthropic, these were practices that were at the initiative of the firm, without any measurable link to improving competitiveness but borne out of a sense of duty. The sense of duty developed from social contract perceptions between firm and communities (Anderson and Paine, 1975; Seechi, 2007). We have also distinguished this from the palliative category because we found no evidence that these practices were linked to specific mitigation of practice of the firm. For example, some organizations offered employments to persons from certain areas out of a sense of duty as opposed to addressing a negative outcome of their operations whilst others provide donations to orphanages and invest in other community-based projects. As one executive alludes;

''*I will say we practice good business and also help our neighbors and local communities when possible. Some of the people employed here today are from the community and the business donates to good educational causes from time to time*" – Manager W1"

Whilst we have used differing lexes to classify our themes, the terminologies do not necessarily represent new ideas about sustainability rather their importance is attached to evidence of incremental difference from the extant literature in the application by organizations within different contexts. For example, although the literature has examined sustainability and competitiveness (Palsson and Kovacs, 2014), sustainability and size (Gallo and Christensen, 2011), the relationship between sustainability, competitiveness and size is yet to be discussed. Our findings already suggest that contextual factors may have intervening effects on this presumed relationship with useful knowledge implications for management. In linking theory, we explored the range of themes and matched them to each of the discussed theories; RBV, RSCR and Stakeholder (Table 1).

Table 1-Thematic and Theory Matrix

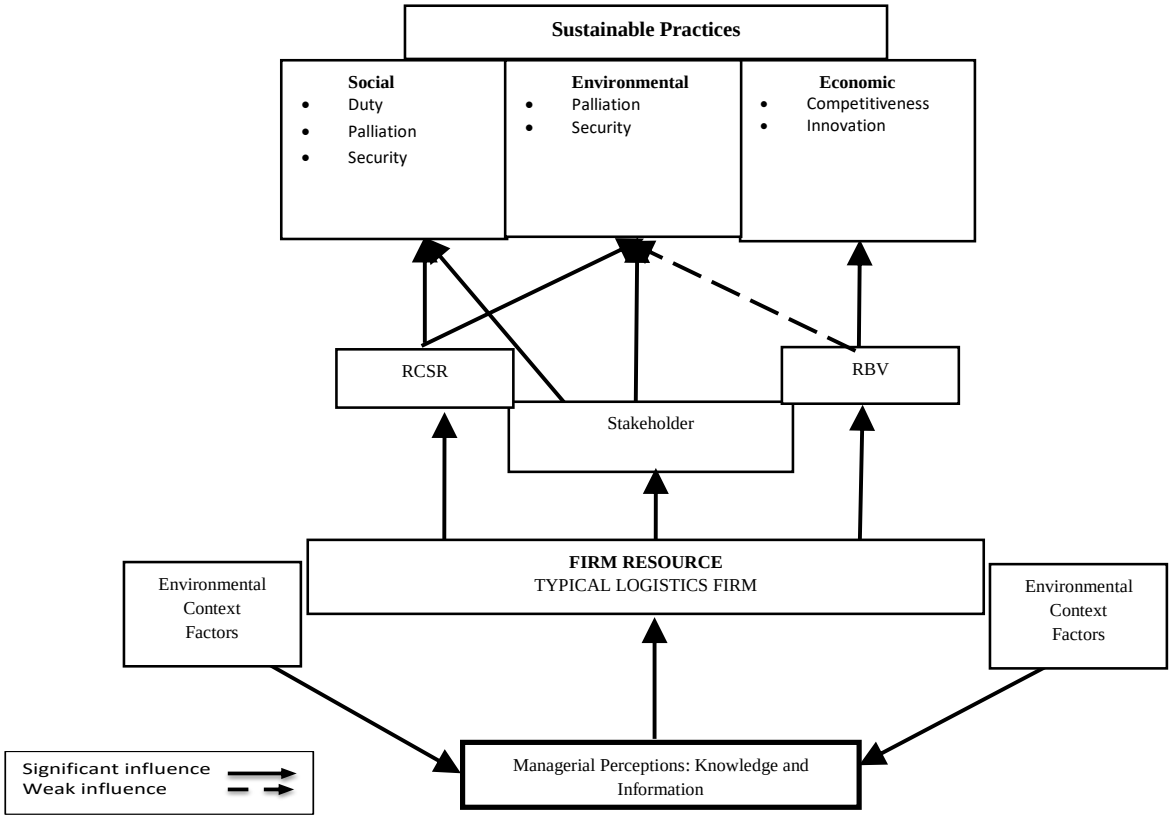
Theme / Theory	Competitiveness	Palliation	Duty	Security	Innovation
RBV	✔			✔	✔
Stakeholder	✔	✔		✔	✔
RCSR		✔	✔		

RBV proponents conceptualize the firm as a bundle of heterogeneous resources that are coordinated towards sustainable competitive advantage (Penrose, 1959; Barney, 1991; Hoskisson et al., 1999). Firm resources assume both tangible and intangible characteristics with emphasis on the ability of the firm to routinely coordinate these resources as a basis for competitive advantage (Grant, 1991). Sustainable practices are largely intangible and there are clear links between sustainability and competitive advantage through profits, operations efficiencies and cost leadership (Hall, 1993; Christmann, 2000; Barney 2001). However, we find no evidence to support RBV links with duty, security or palliation. As a largely introspective theory, RBV focuses on internal processes to support firm performance and we consider it an advanced threshold theory beyond normative thresholds (Grant, 1991; Palsson and Kovacs, 2014).

With regards to RCSR, the greater evidence points to its relevance to duty, palliation and security themes. In Sweden where the market context is considered more mature, it was surprising to note that only one of the organizations surveyed reported competitiveness through sustainable practices. We observed that despite claims to sustainability, logistics organizations surveyed largely pursued traditional practices if the option was permissible. Some executives spoke of sunk investments that were bespoken to their operations and the difficulties in measuring data returns from sustainable practices. Duty, palliative and security practice rationales focused on social contract performance as opposed to competitiveness for most firm. We observed differences in the practices across these contexts and even within local regions, affirming claims that contexts give rise to RCSR legitimacy and attendant practices by organizations (Seechi, 2007). Since these practices were outside the remit of competitive and regulatory requirements for these organizations, we linked their implementation to RCSR constructs of duty and legitimacy, stemming from recognized need to act as opposed to acting for competiveness or to comply with regulatory requirements (Marrewijk, 2003; Seechi, 2007). In terms of Stakeholder theory and the data, we observe the most pervasive relevance. With key constructs centered rational, process and transactional stakeholder strategies, we link some low-level competitiveness, security and palliation to stakeholder theory. For example, our findings on palliation and security where organizations actively establish rational relationships between them and certain groups as a basis for actions, is supportive of Freeman's (2010) rational and transactional perspective. In this case, these organizations establish that their activities impact on stakeholders like young persons, real estate holders etc., and undertake corresponding practices that help to mitigate the negative impact of their activities on these groups. However, we found no rational links with duty-based practices. For example, donations to orphanages and hospitals who had no direct relationship or impact from the activities of these companies have no logical links with the concerned organizations whether in terms of transactions, operations process or activity impact (Figure 2).

In revisiting our conceptual framework, the current findings support the value of theory integration in order to better capture sustainability commitment decision influences. We note that the stakeholder theory provides the greatest scope for evaluating sustainable practices and commitment by organizations although its limitations (mapping) can be addressed by the strengths of RCSR and RBV theories. The concluding parts of this investigation will explore the interdependencies of these theories in the conceptualizing sustainability commitment and practices of organizations building on the findings from this preliminary but promising initial result (Figure 2).

Figure 2. Conceptual Framework – Revised integration



CONTRIBUTION AND FUTURE RESEARCH

In this paper, we reflect on the summative findings of our inquiry into the rationales for sustainability commitment by management in transport and logistics organizations. Building on the literature's position regarding the role of information and knowledge on management strategies, we sought to examine theory appropriation for sustainable practices by organizations. We identified three theories; the resource-based view, relational corporate social relationship and stakeholder theories, as having scope for explaining sustainability practices by organizations. We offer a conceptual model to support our thinking, reflecting assumptions on theory scope.

Fundamentally, our findings highlight that the integration of different theories could offer more interpretative scope for understanding management decisions regarding sustainable practices. Similarly, our findings highlight probable impacts of contextual, size and competitive factors on

the sustainable practices of organizations. As a study in progress we cannot offer conclusive arguments in this regard, however, it offers scope for further investigation in the discourse on firm sustainability. The challenges and scope for sustainability remains complex and limit the efficacy of single theory inquiries. Theory integration can support more effective results that can be used to adequately influence management decisions in practice, leading to more rewarding outcomes. The tri-combination of theory constructs can be further refined into useful assessment tools for management application as knowledge bases for sustainability practices.

ABSTRACT

This paper studies sustainable operations dynamics and control with the focus on sustainable continuous process. We develop a dynamic system that describes interactions between different products and operations processes and optimal control model to identify the optimal operations strategies. Also, a bio-based operations system is provided to verify the proposed models. Performance analyses find that the quantities of initial inputs and raw materials flowing into operations systems affect the dynamics of sustainable operations. By controlling initial inputs and the flow rate at materials, we evaluate the impacts of sustainable operations dynamics on the overall operations performance and identify operations strategies.

KEYWORDS: Sustainable production dynamics, continuous process, optimal control, case study, and simulation analysis.

INTRODUCTION

Sustainable operations have received growing attention of policy makers, industrial companies, and researchers in recent years, with the emphasis on economic, social and environmental impacts of firms' operations. According to Lowell Center for Sustainable Production (2016), sustainable operations refers to" the creation of goods and services using processes and systems that are: a) Nonpolluting; b) Conserving of energy and natural resources; c) Economically viable; d) Safe and healthful for workers, communities, and consumers; and e) Socially and creatively rewarding for all working people." However, sustainable operations face new challenges because of dropping demand, fluctuating gas prices, and increasing environmental concerns (Burk, 2010). Therefore, the objective of this paper is to explore the behavior of sustainable operations process, thus effectively controlling negative environ- mental and social impacts and achieving the maximum economic benefits.

Preferably, we focus on the continuous process for sustainable operations such as producing biological products (Eisentraut, 2010), chemicals (Xiao, 2016) and pharmaceutical products (Braal, 2009; Benyahia et al., 2012), since it is more sustainable than batch process (e.g., low raw material use and wastes, and high-energy efficiency) and superior in high productivity and constant product quality. Sustainable continuous operations is a dynamic process because of interrelationship among distinct processes and interactions between products during operations. For instance, in the sustainable operations of industrial chemicals, when substrate flows into the reactors, all substances including raw materials and products affect one another. More- over, as the concentrations of products increase, they inhibit actual output rate and chemical reaction. In particular, toxic by-products reduce the out- put of desired products, pollute the environment, and cause workers' health and safety issues. Therefore, it is necessary to thoroughly look into the dynamic behavior of sustainable operations, explicitly

identify interrelationship and interactions among all entities in the operations systems, and thus de- sign operations controllers that receive feedback from output to optimize sustainable operations performance.

While much research has recognized the growing importance of sustain- able operations, little research in the literature focuses on the dynamics and operations control of sustainable continuous operations be- cause of its operations complexities. For instance, during sustainable continuous operations of bio-based products, the concentration of substrate has the adverse impact on the desired products as it increases to a certain level, while the toxic by-products inhibit microbial growth and the output of de- sired products, and adversely impact the environment and workers' health and safety. Hence, managing the flow rate of substrate and its concentration effectively can reduce the impact of substrate and by-products on desired products, the environment, and workers to improve the output of desired products and sustainability performance. We employ nonlinear dynamics models to formulate the dynamic, sustainable operations process. Dynamic models have widely applied in process system engineering for decades, since they can predict the transient response, and, therefore, can be used to de- scribe process dynamics behavior during operations. For example, dynamic models play a crucial role in the pharmaceutical industry to reduce costs, lower environmental impacts, and improve the quality of the pharmaceutical products, by implementing advanced model-based control. Moreover, we utilize multiple objective optimization techniques to develop an operations control model that can find trade-offs among economic, environmental and social impacts.

This study contributes to the following: a) a unified framework of modeling the dynamics and operations control of sustainable operations that can derive optimal operations strategies for reducing environmental, social impacts, and improving operations efficiency; b) a case study on the sustainable continuous operations of a bio-based product to simulate the proposed dynamics and control models, and to identify optimal operations strategies; and c) insights obtained by comparing empirical results with data collected from the real continuous operations process of the bio-based product. Empirical results on practical case reveal the proposed framework is well suited with sustainable operations in practice, and that effective control on the flow rate of raw materials and the by-products can maximize the output of desired products, while minimizing the negative impact on workers and the environment.

The remainder of the paper is organized as follows. Section 2 reviews the extant literature regarding operations dynamics. Section 3 concerns the unified framework of sustainable operations dynamics and its operations control systems. Section 4 provides case study on sustainable operations of a bio-based product to verify the framework proposed in Section 3. Section 5 reports the empirical studies of the operations dynamics and the operations control tactics of the bio-based product under various operations strategies. Finally, Section 6 concludes the study and discusses future extensions.

LITERATURE REVIEW

Research on operations economics can be classified into two categories in the literature: one with system dynamics based operations modeling and simulation, and the other regarding the development of dynamical system based on nonlinear differential equations.

System dynamics has extensively applied to sustainable operations in the literature. Bockermann et al. (2005) developed two models based on system systems and economics to evaluate different sustainability strategies and concluded that it needs to make every effort on economic, environmental, social and labor policies to achieve sustainable manufacturing. Stave (2010) used participatory system dynamics modeling as a decision support tool for sustainable environmental management, which captures dynamic connections between social and

ecological systems, integrates stakeholder deliberation with scientific analysis, incorporates diverse stakeholder knowledge, and fosters relationships among stakeholders that can accommodate changing in- formation and changing social and environmental conditions. Zhang et al. (2013) presented a conceptual model that utilizes systems dynamics for sustainable manufacturing assessment to interpret the complex interplaying factors at the operational and enterprise levels. Feng and Fan (2014) developed simulation model based on system dynamics simulating the policy of cross- training and considered the effect of worker learning and forgetting and the heterogeneity within worker pool. Their experiments identified the best way that optimized operations line under different cross-training tactics, worker management policies and worker team structures. By system dynamics and case study methods, Shamsuddoha (2015) studied sustainable manufacturing in the poultry livestock sector to solve existing problems to gain economic, social and environmental benefits. They found that integration of the supply chain was able to bring economic, social and environmental sustainability along with a structured operations process.

A significant amount of research has studied the applications of nonlinear dynamics theory to operations dynamics in the literature. Prior research can be found in Radons et al. (2004). Marca et al. (2010) studied continuum models of operations systems and their prototypical control problems driven by hyperbolic partial differential equation, which was used as a constraint of a nonlinear optimization problem. They showed numerical results on optimal start rate for both constant and varying demand and discussed the influence of the nonlinearity of the cycle time on the limits of the reactivity of the operations system. Armbruster and Uzsoy (2012) considered continuous- time operations system and discussed several implementation schemes from discrete-event simulation. In addition, they examined two alternative approaches: discrete-time linear programming modeling based on nonlinear clearing functions, and systems of coupled partial differential equations re- lying on transport phenomena. Yang et al. (2013) proposed a data-driven continuous fluid flow approach for modeling aggregated assembly line dynamics in terms of the principles of nonlinear dynamics theory. They solved this model using real-world data by Matlab and found that this model is of potential use and can provide deeper insights into the dynamics of complex manufacturing systems. Wang and Gunasekaran (2015) developed a mathematical model based on nonlinear dynamic system to describe the dynamics of the impact of supply chains on environment while achieving sustainable supply chains. They proved the existence and uniqueness of its solutions, analyzed its equilibrium and stability, and conducted performance and sensitivity analysis. Tan (2015) considered continuous material flow operations systems and optimal operations flow control problems with unreliable station and deterministic demand. He developed a mixed-integer linear programming formulation for performance evaluation and optimization and showed its validity for continuous material operations systems.

In general, current literature lacks research on a unified framework for sustainable operations dynamics, particularly for operations dynamics of sustainable continuous process. Hence this paper will serve this purpose and, most importantly, explore dynamic behavior of sustainable continuous process and optimal operations strategies to achieve operations sustainability.

SUSTAINABLE PRODUCTION DYNAMICS AND CONTROL

This section presents a comprehensive framework for modeling the sustainable operations dynamics and its optimal operations control systems that seek to maximize the output of desired products and/or economic returns at the least environmental and social impacts.

Dynamics model

Operations dynamics is governed by complex, inherent interdependence of inputs and outputs and various interacting operations processes.

Sustainable repetitive manufacturing systems associated with assembly lines are often modeled in an aggregate fashion. However, modern manufacturing system is a huge network consisting of many operations and storage facilities. Raw materials, parts, or subassemblies flow into operations systems and produce finished products through a sequence of operations in different facilities. Such manufacturing systems manifest nonlinear dynamics and the internal flows are explicitly formulated as continuous-flow operations, in terms of nonlinear dynamics theory as studied by (Sharifnia, 1994), Scholz- Reiter et al. (2002) and Radons et al. (2004). This is because continuous-flow models are simple and computationally advantageous in a decentralized fashion (Sharifnia, 1994). On the other hand, continuous process plays a vital role in sustainable operations such as in bio-based operations and in pharmaceutical industry. The continuous process in sustainable operations consists of water tanks and pipes as well as product and by-product flows, where entities including materials, desired products, and by-products flow through a system of tanks connected by pipes. Valves controls the flow rates of entities, and the time spent in each tank is dependent on the rates of influx and outflow. The quantities of inputs and products in each tank change continuously over time. Figure 1 illustrates the continuous process of sustainable operations below.
Throughout the entire transformation, however, various processes as well as different inputs and outputs interact dynamically, which shows nonlinear correlation.

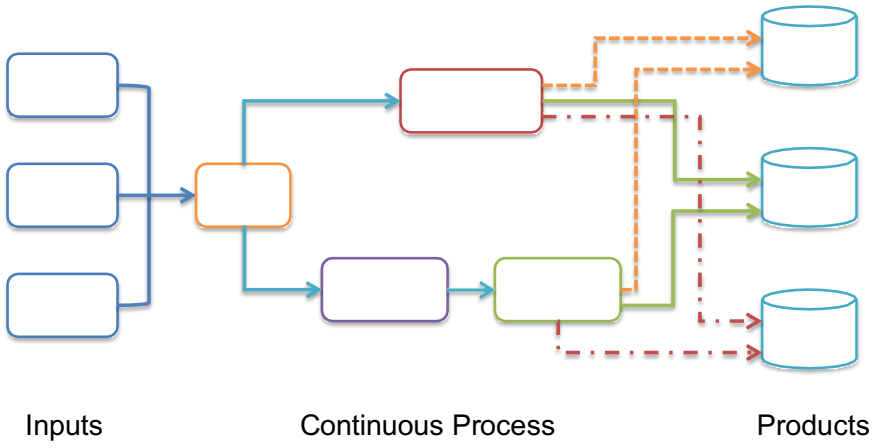

Figure 1: Continuous process in sustainable operations

To develop efficient and effective operations strategies, we present an integral framework of dynamic model of sustainable operations in the following.

$$\dot{\boldsymbol{x}}(\boldsymbol{t}) = \boldsymbol{f}\big(\boldsymbol{x}(\boldsymbol{t}), \boldsymbol{u}(\boldsymbol{t})\big), \forall\, \boldsymbol{t} \in (\boldsymbol{0}, \boldsymbol{T}), \boldsymbol{x}(\boldsymbol{0}) = \boldsymbol{x_0} \quad (1)$$

where $\boldsymbol{x}(\boldsymbol{t})$ denotes the quantities and/or concentrations of all inputs and/or products at time *t*, called system state. $\boldsymbol{x_0}$ refers to the initial inputs of sustainable operations process, including required raw materials, parts, or sub-assemblies for sustainable operations. We can partially achieve effective control on sustainable operations by adjusting $\boldsymbol{x_0}$. $\dot{\boldsymbol{x}}(\boldsymbol{t})$ is the operations rate or the change of quantities of inputs and/or products, which is concurrently affected by the

quantities and/or concentrations of all entities being produced and/or being consumed in the operations systems, as well as the quantities and/or concentrations of raw materials, parts or components entering operations systems. $\boldsymbol{f(x)}$ is a nonlinear vector field and describes dynamic correlations between different inputs and products. $\boldsymbol{u(t)}$denotes time-varying operations control strategies, measures and gives feedback on sustainable operations performance in real time, thus fulfilling optimal performance management. In the case of industrial chemicals operations, effectively controlling substrate concentration can shorten reaction time, increase the output of desired products, and mitigate the impacts of by-products. $\boldsymbol{T} \in (\boldsymbol{0}, \infty)$ denotes the time at which dynamic systems reach steady state. Furthermore, we introduce notations to facilitate our analysis and simulation as follows. Let $\boldsymbol{U_{ad}}$ be the set of admission operations control strategies and then it follows that $\boldsymbol{u(t)} \in \boldsymbol{U_{ad}}, \forall\, \boldsymbol{t} \in [\boldsymbol{0}, \boldsymbol{T}]$. Given any $\boldsymbol{u(t)}$, let $\boldsymbol{W}$ denote the state space of studied dynamic systems, i.e., $\boldsymbol{W} = \{\boldsymbol{x(t)} \in \boldsymbol{R^n} | \dot{\boldsymbol{x}}(\boldsymbol{t}) = \boldsymbol{f}\big(\boldsymbol{x(t)}, \boldsymbol{u(t)}\big), \forall \boldsymbol{t} \in [\boldsymbol{0}, \boldsymbol{T}]\}$.

Operations control

This subsection presents a framework of operations control on sustainable operations systems that attempts to seek compromise between economic benefits, and social and environmental concerns.

Sustainable operations process not only produces desired products, but also generates toxic by-products. Desired products bring in revenues to organizations, while by-products are harmful to workers and the environment. Sustainable operations place a strong emphasis on economic, social and environmental aspects, so it is essential to achieve effective operations control on sustainable operations. Hence, we develop a multiple objective optimal operation control model to find the best operations strategies with the objectives of maximizing the output of desired products and, at the same time, minimizing the social and environmental impacts of by-products.

Let $\boldsymbol{G_n}$ denote Hessian matrix, $\boldsymbol{n} = \boldsymbol{1, 2, \cdots, N}$, and $\boldsymbol{x(T, u)}$ be the quantities and/or concentrations of final products in operations systems at time $\boldsymbol{T}$, i.e., the final products' quantities and/or concentrations when dynamic systems reach steady states. Using multiple objective optimization techniques, the sustainable operations control systems (P) can be formulated in the following.

$$\textbf{max} \quad \boldsymbol{J_1(u) = x(T,u)^T G_1 x(T,u)/T^2} \tag{2}$$

$$\textbf{max} \quad \boldsymbol{J_n(u) = x(T,u)^T G_n x(T,u)\ /T^2, n = 1, 2, \cdots, N} \tag{3}$$

$$\textit{s.t.}\ \boldsymbol{x} \in \boldsymbol{W}, \tag{4}$$

$$\boldsymbol{u} \in \boldsymbol{U_{ad}}, \tag{5}$$

$$\boldsymbol{x(0) = x_0}. \tag{6}$$

The first objective (2) is to maximize the amount of desired product, while the second (3) is to minimize the use of resources and the output of by-products as toxic by-products have harmful impacts on workers and the environment. Constraint (4) ensures that sustainable operations process satisfies the dynamics characteristics described by dynamic systems (1). Constraint (5) states that control variables $\boldsymbol{u(t)}$ vary in the admission operations control set, $\boldsymbol{U_{ad}}$. Constraint (6) implies the inputs of resources for sustainable operations processes. Throughout the remaining parts, we shall denote the operations control problem as (*P*).

To solve (*P*), we introduce a weighing factor *λ* indicating operations managers' preference, thus converting (*P*) into a single objective problem. Let $\boldsymbol{\lambda_n} \geq \boldsymbol{0}$ denote weights satisfying $\sum_{\boldsymbol{n=1}}^{\boldsymbol{N}} \boldsymbol{\lambda_n} = \boldsymbol{1}, \boldsymbol{n} = \boldsymbol{1, 2, \ldots, N}$, and, by weighing (2) and (3), (*P*) can be written below.

(*SP*) $\max\ J(u) = \lambda_1 J_1(u) - \sum_{n=1}^{N} \lambda_n J_n(u)$ (7)
s.t. (4), (5), and (6). (8)

(SP) attempts to find a comprise among economic, environmental, and social concerns and allows for the importance of different impacts that operations managers perceive. For instance, when three entities are involved in the operations, suppose that λ_1 takes the value of greater than $\frac{1}{3}$, which means that operations managers see economic benefits as more important than environmental and social impacts. Hence, these operations control models offer operations managers a decision-making tool to evaluate different scenarios (e.g., government regulations, corporate policies, operations strategies) and their impacts on overall operations performance.

CASE STUDY: CONTINUOUS PROCESS OF 1,3-PD SUSTAINABLE OPERATIONS

This section introduces a case study on the sustainable operations of 1,3-propanediol(1,3-PD) and presents its operations dynamics and optimal operations control models. The bio-based 1,3-PD is a high-performance, sustainable building block material and replaces petroleum-derived materials. 1,3-PD has been adopted by leading manufacturers in a variety of consumer and industrial markets, since it not only provides unique performance advantages, but can also reduce environmental footprint and harms to workers' health and safety (Molel et al., 2015).

1,3-PD operations dynamics

The sustainable continuous process of 1,3-PD starts with the flow of substrate (e.g., glycerol) into the reactor at a certain rate, and, over a period of time, some products (e.g., 1,3-PD, acid, and ethanol) flow out of the reactor at the same rate, while keeping the entire volume of reactor constant (Wang et al., 2007). For the purpose of modeling 1,3-PD operations dynamics, we assume that substrate perfectly intermixes and inputs and outputs are uniformly distributed in the reactor. Furthermore, during the reaction process, substrate flowing into the reactor only includes glycerol and products flow out at the dilution rate *D* (Wang et al., 2008).

Let $\boldsymbol{f(x)} = (\boldsymbol{f_1(x), f_2(x), f_3(x), f_4(x), f_5(x)})$, $\boldsymbol{x_1(t), x_2(t), x_3(t), x_4(t), x_5(t)}$, be biomass, glycerol, 1,3-PD, acetate and ethanol concentrations at time *t* in reactor, respectively, *D* be the dilution rate, and C_0 denote the feeding glycerol concentration. Hence, continuous process dynamics for producing 1,3-PD can be formulated in the following.

$$\boldsymbol{f_1(x) = (\mu(x) - D)x_1}, \quad (9)$$
$$\boldsymbol{f_2(x) = D(C_0 - x_2) - q_2(x)x_1}, \quad (10)$$
$$\boldsymbol{f_3(x) = q_3(x)x_1 - Dx_3}, \quad (11)$$
$$\boldsymbol{f_4(x) = q_4(x)x_1 - Dx_4}, \quad (12)$$
$$\boldsymbol{f_5(x) = q_5(x)x_1 - Dx_5}, \quad (13)$$

where $\boldsymbol{\mu}$ denotes the specific growth rate of cells, $\boldsymbol{q_2}$ refers to specific consumption rate of substrate, and $\boldsymbol{q_i, i = 3,4,5}$, represent specific formation rate of 1,3-PD, acid, and ethanol, respectively, which are expressed by the following equations on the basis of previous work (Wang et al., 2009).

$$\boldsymbol{\mu = \mu_m \frac{x_2(t)}{x_2(t)+k_s} \prod_{i=2}^{5} (1 - \frac{x_i(t)}{x_i^*})} \quad (14)$$

$$\boldsymbol{q_2 = m_2 + \frac{\mu}{Y_2} + \triangle_2 \frac{x_2(t)}{x_2(t)+k_2}} \quad (15)$$

$$q_i = m_i + \mu Y_i + \Delta_i \frac{x_2(t)}{x_2(t)+k_i}, i = 3,4 \quad (16)$$

$$q_5 = q_2\left(\frac{b_1}{Dx_2(t)+c_1} + \frac{b_2}{Dx_2(t)+c_2}\right) \quad (17)$$

In Equation (14), $\mu_m = 0.67g/h$ denotes the maximum specific growth rate of cells under anaerobic conditions when temperature is 37°C and $pH = 7.0$; $k_s = 0.28$ is Monod saturation constant; and $x_1^* = 10g/L, x_2^* = 2039mmol/L, x_3^* = 939.5mmol/L,\ x_4^* = 1026mmol/L$ and $x_5^* = 360.9mmol/L$ represent the critical concentrations of biomass, glycerol, 1,3-PD, acetate and ethanol. In Equations (15) - (17), $m_i, Y_i, \Delta_i, k_i, i = 2,3,4$, and $b_1 = 0.025,\ b_2 = 0.06,\ c_1 = 5.18, b_2 = 50.45$ are model parameters, whose values are identified through experiments and listed in Table 1 from the previous work (Wang et al., 2007).

Table 1: The values of the parameters in Equations (15) and (16)

Parameters	m_2	m_3	m_4	Y_2	Y_3	Y_4	Δ_2	Δ_3	Δ_4	k_2	k_3
Values	2.20	-2.69	-0.97	0.0082	67.69	33.07	28.58	26.59	5.74	11.43	15.50

Control problem

1, 3-PD is the desired product, while acid and ethanol are both by- products that are hazardous to the environment and workers and also inhibit the output of 1,3-PD. To improve the output of 1,3-PD and reduce the impact of harmful by-products, we present an operations control model for sustainable operations of 1,3-PD. Specifically, the operations control model uses the productivity of 1,3-PD as cost functional, and utilizes the output concentrations of acetate and ethanol as the objectives for social and environmental concerns, based on 1,3-PD's continuous operations dynamics (9)- (13). Let $W = \{x \in R^5 \mid x\ satisfies\ (9), (10), (11), (12), and\ (13)\}$ and $U_{ad} = \{u \in R \mid u(t) \in [0.01, 0.3],\ \forall t \in [0, T]\}$. Then operations control model for 1,3-PD's sustainable operations is formulated below.

(P_1) $\quad \max \quad J_1(u) = x_3(T,u),$
$\min \quad J_2(u) = x_4(T,u),$
$\min \quad J_3(u) = x_5(T,u),$

$s.t \quad x \in W, u \in U_{ad}.$

where the first objective J_1 attempts to maximize the output of 1,3-PD, and the second and the third are to minimize the output of by-products, acid and ethanol. By introducing the management's preference, $\lambda_n, n = 1,2,3$, the corresponding weighted sum problem can be written as follows.

(P_2) $\quad max\ J(u) = \lambda_1/J_1(u) - \lambda_2 J_2(u) - \lambda_3 J_3(u)$
$s.t \quad x \in W, u \in U_{ad}.$

Where $\sum_{n=1}^{3} \lambda_n = 1$.

EMPIRICAL STUDY

This section continues with the above-mentioned case study with the focus on evaluating the performance of the proposed operations dynamic model and identifying the optimal operations control strategies for 1,3-PD sustainable operations.

Performance analysis

We shall validate the proposed dynamic model of 1,3-PD in comparison with experimental data, and analyze the impacts of dilute rate and the concentrations of biomass and substrate on operations dynamics.

Validation of dynamics model

Given experimental data, the dynamic model (9) - (13) is validated through solving the system of differential equations with $x_{01} = 0.115g$, $x_{02} = 495mmol/L$, $D = 0.1L/h$, and $T = 100$ hours as shown in Figure 2. The blue solid lines denote simulated results based on dynamics model, while green dots represent experimental data.

Figure 2 compares the concentration variations of biomass, substrate, 1,3-PD, acetate, and ethanol between simulated results and experimental data over a period of 100 hours in the reactor. The first thing to note is that simulated results on the concentrations of substrate and 1,3-PD fit better with experimental data than those with biomass, acetate, and ethanol throughout the whole time frame. To begin with, concentration variations of biomass, 1,3-PD, acetate, and ethanol follow a fairly similar pattern over the period. The general trend is that their concentrations grow rapidly in the initial stage of reaction, reach a peak, and then decline to constant, which implies that dynamics system reaches steady states. In contrast, substrate's concentration experiences a downward trend, starting at 495*mmol/L*, drop- ping to approximately 50*mmol/L*, and then rising to steady states around 90*mmol/L*. It can be seen that this dynamic model is well established as simulated results show such much similar trend as experimental data do in terms of concentration variations of biomass, substrate, 1,3-PD, acetate, and ethanol.

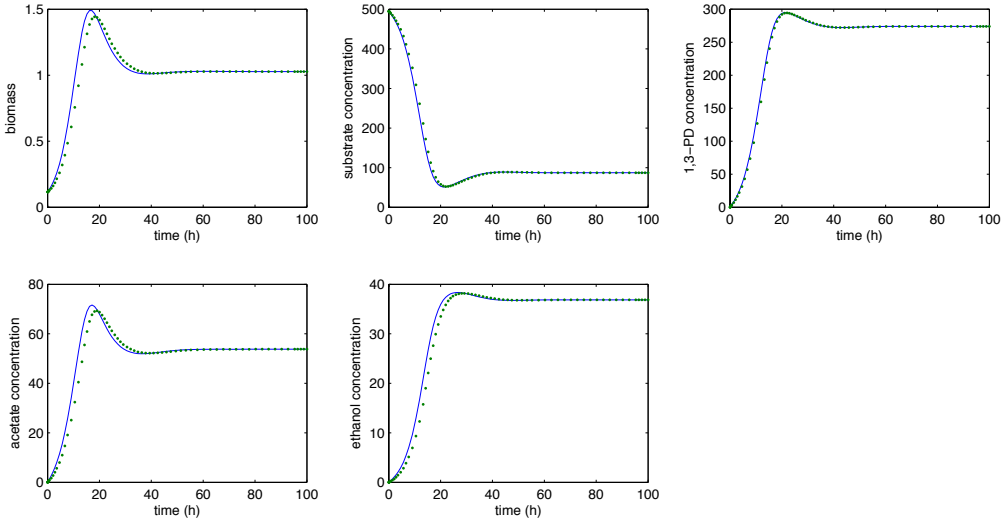

Figure 2: Comparison between simulated results and experimental data over the period of 100 hours

Impact of initial biomass on dynamics

To evaluate the impact of initial biomass on operations dynamics, we set x_{02} = 495*mmol/L*, D = 0.1*l/h*, and T = 100 and solve the dynamic model (9) - (13) when x_1 = 0.115*g,* 0.3*g,* 0.5*g,* 0.7*g*, respectively. The simulated results are shown in Figure 3, where blue solid lines, green dots, red cross, and light blue dash lines denote concentration variations of biomass, substrate, 1,3-PD, acetate, and ethanol, respectively, corresponding to different initial biomass concentrations. Specifically, Figure 3 illustrates the concentration variations of biomass, substrate, 1,3-PD, acetate, and ethanol over the period of 100 hours when initial biomass concentration increases from 0.115 to 0.7. Overall, with different initial biomass concentrations, the concentrations of biomass, 1,3-PD, acetate, and ethanol rise more sharply, while substrate's concentration declines more steeply over the period. Furthermore, the growth in initial biomass concentration also results in the increase in the highest concentrations of biomass, 1,3-PD, acetate, and ethanol. For example, the concentrations of biomass, 1,3-PD, acetate, and ethanol reach peak at approximately 1.45*g*, 295*mmol/L*, 70*mmol/L*, 48*mmol/L*, respectively, with x_{01} = 0.115*g*; they peak at around 1.85*g*, 300*mmol/L*, 73*mmol/L*, 40*mmol/L*, with x_1 = 0.7*g*. Hence it can be seen that initial biomass concentration has a huge impact on biomass concentration over the period. It is apparent that excess biomass needs to consume more substrate to meet its growth needs, which explains the reason why substrate concentration drops steeply when initial biomass concentration varies. Although the concentrations of 1,3-PD, acetate, and ethanol follow very similar patterns, increasing initial biomass concentration has a slight impact on the highest concentrations of 1,3-PD, acetate, and ethanol over the period. Similarly, the increase in initial biomass concentration has a small impact on the lowest concentration of substrate, starting at nearly 50*mmol/L* when x_{01} = 0.115*g* and ending at almost 40*mmol/L* when x_1 = 0.7*g*. In conclusion, the increase in initial biomass concentration has slight impact on the highest concentrations of 1,3-PD, acetate, and ethanol, and the lowest concentration of substrate, while it significantly affects the rate of change of biomass, substrate, 1,3-PD, acetate, and ethanol over the period in the reactor.

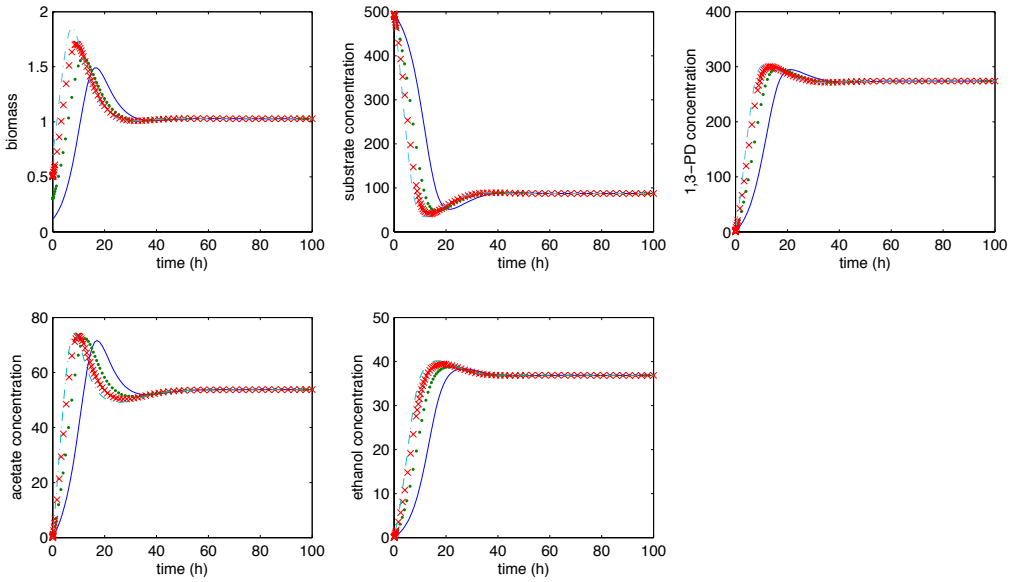

Figure 3: Concentration variations of biomass, substrate, and 1,3-PD over the period of 100 hours with x_1 = 0.115, 0.3, 0.5, 0.7

Impact of initial substrate concentration on dynamics

Since substrate serves as the basis of biomass growth, the impact of initial substrate concentration on operations dynamics is analyzed, when it takes the value of 495*mmol/L,* 600*mmol/L,* 800*mmol/L,* 1000*mmol/L*, respectively. Here, the respective initial biomass concentration and dilute rate are set to x_{01} = 0.115*g* and D = 0.1*L/h*. Figure 4 shows the changes on the concentrations of biomass, substrate, 1,3-PD, acetate, and ethanol when initial substrate concentration rises. Blue solid lines, green stars, red cross, and light blue dashed lines denote the impacts of initial substrate concentration, x_{02} = 495*mmol/L,* 600*mmol/L,* 800*mmol/L,* 1000*mmol/L*.

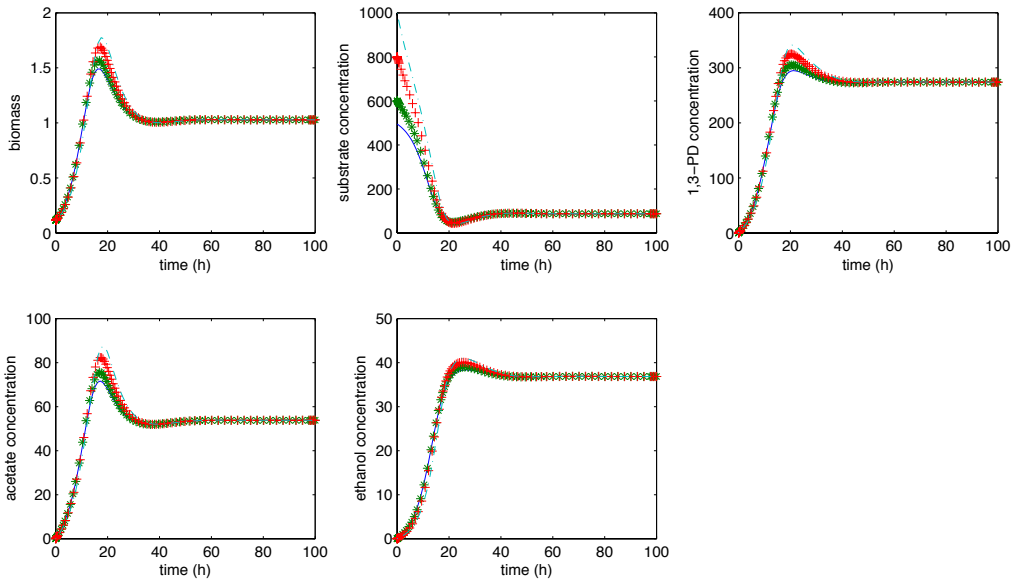

Figure 4: Concentration variations of biomass, substrate, and 1,3-PD over the period of 100 hours with x_2 = 495, 600, 800, 1000

Overall, increasing initial substrate concentration has the significant impact on the maximum concentrations of biomass, 1,3-PD, and acetate, while it has the small impact on the lowest concentration of substrate and the highest concentration of ethanol. The increase in substrate's concentration in the reactor provides more substances for biomass to grow, so the highest biomass con- centration reaches up to 1.8*g* when x_{02} = 1000*mmol/L*, compared to under 1.5*g* when x_{02} = 495*mmol/L*. Accordingly, 1,3-PD concentration increases from 300*mmol/L* to roughly 340*mmol/L*. Furthermore, it is observed that the increase in the initial substrate concentration does not impact the rate of concentration changes throughout the period. Hence we can conclude that initial substrate concentration has little impact on the concentrations of biomass, 1,3-PD, acetate, and ethanol during the period in the reactor.

Impact of dilute rate on dynamics

We consider the following initial concentrations for biomass and substrate, $x_{01} = 0.115g$ and $x_{02} = 495mmol/L$ and aim to examine the impact of dilute rate on operations dynamics. Figure 6 demonstrates such impacts of dilute rate, D, specifically, on the concentrations of biomass, substrate, 1,3-PD, acetate, and ethanol over the period of 100 hours. Blue solid lines, green stars, red crosses, and light blue dashed lines represent the impact of different di- lute rates, where $D = 0.1L/h$, $015L/h$, $0.2L/h$, $0.25L/h$, $0.3L/h$. In general, dilute rates have huge impacts on the rate of concentration changes, maximum concentrations of biomass, 1,3-PD. acetate, and ethanol, as well as the lowest substrate concentration. When dilute rate starts with $D = 0.1L/h$, the concentrations of biomass, 1,3-PD, acetate, and ethanol grow dramatically up to the maximum, whereas substrate concentration drops rapidly to the minimum. As dilute rate moves up towards $0.3mmol/L$, the maximum concentrations of biomass, 1,3-PD, acetate and ethanol fall substantially and the growing rate of their concentrations also deceases. In the mean- while, substrate concentration drops very slowly and reaches steady state at around $300mmol/L$ when $D = 0.3L/h$, compared to steady-state concentration of $50mmol/L$ when $D = 0.1L/h$. In addition, it is important to note that dilute rate has considerable impact on the time when dynamic system reaches steady state. The system reaches steady state at approximately $20h$ when $D = 0.1L/h$, while it starts to enter steady state at around $40h$ *given* $D = 0.3L/h$. It follows that dilute rates have huge impact on the dynamics of 1,3-PD's sustainable operations, so it is necessary to control dilute rate in order to achieve the tradeoff between social, environmental concerns, and economic benefits.

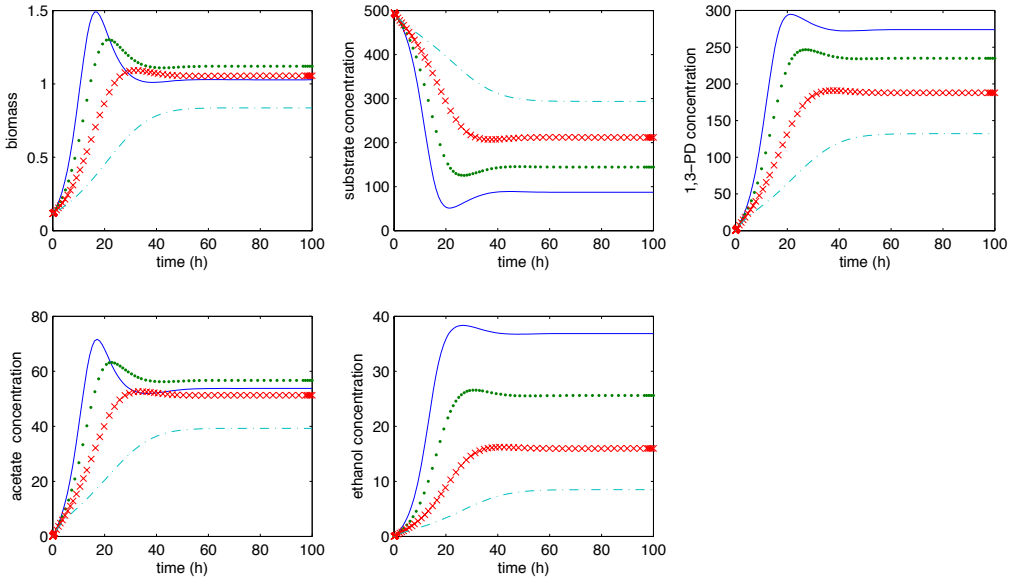

Figure 5: Concentration variations of biomass, substrate, and 1,3-PD over the period of 100 hours with $D = 0.1L/h$, $0.15L/h$, $0.2L/h$, $0.25L/h$, $0.3L/h$

Optimal operations control strategies

From the above analysis on Figure 6, it can be seen that substrate's dilute rate has the significant impact on the concentrations of biomass, substrate, 1,3-PD's, and by-products. This subsection concerns controlling the flow rate of substrate into reactor so optimally as to find a tradeoff between maximizing the output of 1,3-PD and minimizing adverse impact of acetate

and ethanol on workers and the environment. In this case study, we choose x_0 = (0.115*g/L,* 495*mmol/L,* 0*,* 0*,* 0)^T as the initial concentrations for biomass and substrate, respectively. Using hybrid particle swarm optimization algorithm presented by Wang et al. (2009), we obtain an optimal operations control policy for (P_1), D^* = 0.06*L/h*. Figure 1 gives steady-state concentrations of 1,3-PD, acetate, and ethanol as dilute rate, *D*, varies from 0.01*L/h* to 0.3*L/h*, where blue dot sign denotes the variation on steady-state concentration of 1,3-PD over *D*, red cross sign represents the change on steady-state concentration of acetate over *D*, and pink plus sign shows the trend of steady-state concentration of ethanol over *D*. The maximum of 1,3-PD obtained by (P_2) is 293.99*mmol/L*, while the minimums of acetate and ethanol are 41.93*mmol/L* and 47.35*mmol/L*, respectively.

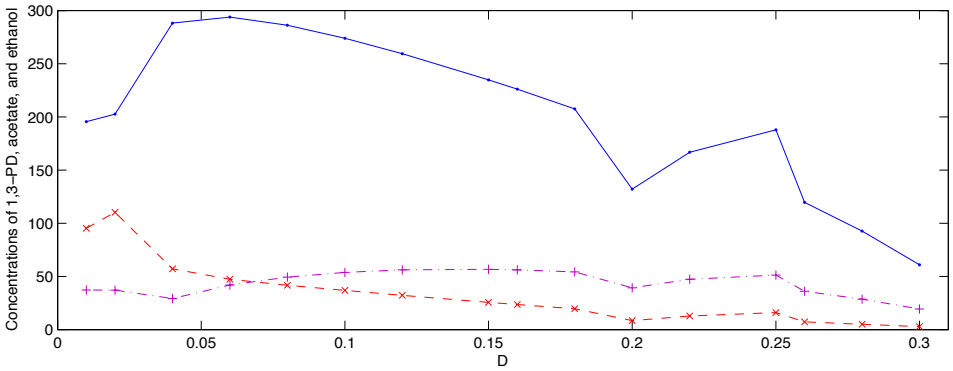

Figure 6: Steady-state concentrations of 1,3-PD, acetate, and ethanol as *D* varies between 0.01*L/h* and 0.3*L/h*

CONCLUSION AND FUTURE EXTENSIONS

Although sustainable operations have received growing interest in industries and academia, research in the literature has not fully investigated the dynamics and operations control of its continuous process. Since inputs, desired products, and by-products interact in operations process, sustain- able continuous operations presents dynamics characteristics. This study aims to achieve efficient and effective operations management on sustainable operations by studying its dynamics and operations control. This paper presented a comprehensive framework for operations dynamics of sustainable continuous process, based on nonlinear dynamical systems. Also, we offer an operations control model, taking into account economic, environmental, and social impacts. To solve this control model, we developed a compromising model by introducing weighing factors to different impacts. It attempted to find trade-offs that can minimize environmental and social impacts while maximizing economic benefits. Then a real case confirmed the proposed dynamics and control models and tested the impacts of inputs on operations dynamics. Simulated results showed the appropriateness and robustness of the proposed dynamics and operations control systems. Our research on real case found that initial inputs and materials flowing into operations systems significantly affect the dynamics of sustainable operations. Hence, control- ling initial inputs and the flow rate of materials in operations process enables us to optimize sustainable operations performance.

There are three major extensions for this research. One is on the design of effective algorithms for solving operation control problems. A good algorithm can help operations controllers to quickly find the best operations strategies in response to unexpected changes that occur in operations process. The other is to extend the results developed in this paper to design

robust, adaptive sustainable operations systems in the big data context. Operations controllers adjust the flow rate of materials by analyzing real-time data from sensors, thereby directing dynamics systems towards optimal sustainable operations. Also another possible extension is to develop a probability model that captures random behavior and nonlinear dynamics for both repetitive and continuous processes. Moreover, developing stochastic operations control models manages dynamic, stochastic operations processes, thus optimizing sustainability performance.

ABSTRACT

Supply chain management is essential to company success and customer satisfaction. In this case study, we use the historical data to forecast the demand for each client and develop an optimisation model to plan for the production such that total cost which includes shipping cost, holding cost and production cost will be minimised. Developing a spreadsheet model here helps the company to determine the best production plan to meet the demand subjected to operational constraints.

KEYWORDS: Keywords: forecasting, inventory management, shipping cost, production planning, spreadsheet modelling, optimization.

1 INTRODUCTION

Advance Cable Manufacturing Sdn. Bhd. is a privately held, employee stock ownership company with a rich history dating back to 1904. The company started off as a steel foundry in the earlier part of century producing cast iron and other metal products. As the economy modernises, the company diversifies its product base to include different types of metal related products such as wires. The wire products became a profitable line and soon displaces other products which are manufactured in more cost-efficient locations.

2 BACKGROUND

Cable manufacturers in Southeast Asia have recently faced stiff competition from goods produced in China and Germany. Even with the various transportation cost and tariffs, China-produced cables are much cheaper than their Southeast Asian counterparts because of inexpensive labour and factory operation. Germany dominates the high-end cable manufacturing market with competitive pricing due to the EU free trade zones or speciality cables. As Advance Cable Manufacturing Sdn. Bhd. produces both cheaper and more specialised wires, it comes under stiff competition from both global players regarding quality and cost.

Advance Cable Manufacturing Sdn. Bhd. has been able to maintain its market presence in the face of low cost and speciality foreign competition primarily because of its reputation in the cable market. Be it working with customer supplied specification or catering to a unique requirement, Advance Cable Manufacturing Sdn. Bhd. design teams develop innovative, one-of-a-kind wire and cable solutions to solve its client business problems. On-site manufacturing processes include wire drawing, plating, braiding, cabling and extrusion services. And, since all the proprietary equipment and tooling is designed and built in-house, the company has complete control while also offering flexibility when needed. Through vertical integration of manufacturing processes, the customers' design-to-market curve is the shortest in the industry.

3 BUSINESS SETUP

Advance Cable Manufacturing Sdn. Bhd. serves 8 major clients (clients 1, 2, 3, 4, 5, 7, 8, and 9) and each customer has its distribution network in different countries. The clients are consumer electronics and industrial goods manufacturers. In each country, the sales volume comprises of sales in different products lines such as Goods, Appliances and Industry, Desktop, Lamp and Smartphone. Below is the detailed sales volume composition which is broken down into constituent products for each customer in each country.

8	Greater China	29%	18%	14%	33%	6%
	India	37%	21%	15%	13%	14%
	Korea	44%	6%	5%	12%	33%
	SEA	27%	13%	2%	29%	29%
9	Greater China	12%	19%	33%	21%	15%
	India	12%	38%	27%	12%	11%
	Japan	1%	16%	35%	29%	19%

Table 1: Sales Volume Composition by Products for Each Customer in Each Country

To simplify the process of manufacturing, storage and shipping, Advance Cable Manufacturing Sdn. Bhd. produces the components for each particular product line which then gets assembled at the destination by the customers according to their design specifications. This specific process reduces the cost of manufacturing while extending the product flexibility for customers.

Table 2 below shows the breakdown of the components required for different products, also known as the bill of materials (BOM). From Table 2, we can see that for each unit of Desktop, you will need 3 of component 1, 1 component 5 and 2 component 6. Each unit of Smartphone will require 1 unit of component 1 and 2 unit of component 2. The same logic applies to the other products.

	Components			
Products	**1**	**2**	**5**	**6**
Goods	1	2	1	0
Appliances and Industry	0	2	1	1
Desktop	3	0	1	2
Lamp	1	4	0	2
Smartphone	1	2	0	0

Table 2: Bill of Materials for Each Product

Advance Cable Manufacturing Sdn. Bhd. has 4 core production facilities (**P1, P4, P5 and P7**) in different parts of Malaysia whose sole focus is manufacturing and quality testing. Production plant **P1** is located in Alor Seta, **P4** is located in Miri, **P5** is located in Kuala Terengganu and **P7** is located in Kota Kinabalu. As an ISO9001:2008 certified company, the company has more than 600 employees operating three shifts, five days a week.

The production plants operate state-of-the-art machines which produce the wire components efficiently. Due to some production limits, it is not uncommon for the production plants to transship the components among themselves to meet customer's demand. The company has a strict policy where only the same component that is produced by two plants can be

transshipped. This is due to storage facilities required to ensure the quality of the components is maintained as inventory. The transhipment between any 2 plants will take around 1 month. Production of the components also takes 1 month. The various production plants have different production volume limits and unit production costs as well. Table 3 and 4 below are the detailed breakdowns of the production volume limit and cost of production.

Plant	P1		P4	P5		P7
Components	5	6	2	5	6	1
201201	12348441	12691851	25040292	55469840	59291481	40670920
201202	12348441	12691851	12520146	55469840	59291481	40670920
201203	13801624	12224245	26025869	52378450	57722070	11640533

Table 3: Production Volume Limits (Per Unit of Item) for 2012 at Different Plants

Plant Location	P1	P4	P5	P7
201201	$2.98	$4.99	$2.33	$2.87
201202	$1.05	$4.25	$1.79	$4.37
201203	$3.37	$4.18	$3.17	$4.87
201204	$1.91	$4.02	$4.40	$2.87
201205	$3.85	$1.98	$3.76	$1.02
201206	$4.26	$2.11	$4.08	$2.78
201207	$3.70	$2.72	$1.41	$2.83
201208	$4.70	$2.70	$1.40	$2.52
201209	$3.93	$4.72	$2.13	$4.72
201210	$1.33	$3.04	$1.85	$4.36
201211	$2.16	$4.93	$2.62	$2.04
201212	$3.58	$1.56	$2.85	$4.25

Table 4: Unit Production Costs for 2012 at Different Plants

The production plants P1 and P5 produce the same components, and as a result, should there be any shortfall, the components can be transshipped between the plants before getting shipped to the countries that they each serve. Below is the breakdown of the transhipment volume limits and unit costs of transhipment between the 2 plants.

Production Plant Transshipment	P1		P5	
Component Supplies	**5**	**6**	**5**	**6**
201201	$3.51	$1.85	$1.31	$1.74
201202	$3.44	$4.23	$4.77	$2.01
201203	$4.86	$1.36	$1.64	$2.25
201204	$3.33	$4.12	$4.41	$4.49
201205	$4.41	$3.89	$4.91	$2.00
201206	$3.31	$4.46	$3.13	$2.68
201207	$3.42	$1.90	$3.16	$1.81
201208	$1.92	$1.17	$1.07	$2.86
201209	$2.07	$1.21	$4.92	$3.00
201210	$2.7	$3.13	$1.07	$3.24
201211	$4.98	$4.42	$1.68	$4.54
201212	$3.38	$3.85	$1.29	$2.08

Table 5: Unit Transshipment Costs for Each Component for 2012 out from Each Plant

Production Plant Transshipment	P1		P5	
Component Supplies	**5**	**6**	**5**	**6**
201201	2100000	1300000	2500000	4500000
201202	0	1100000	2500000	1100000
201203	0	0	2500000	1100000
201204	0	0	2500000	1100000
201205	0	0	3500000	1100000
201206	0	0	3500000	4500000
201207	0	0	3500000	4500000
201208	0	0	4500000	4500000
201209	0	0	4500000	4500000
201210	0	0	4500000	4500000
201211	0	0	4500000	4500000
201212	0	0	0	0

Table 6: Transshipment Volume Limits for 2012 out from Each Plant

The various production plants produce various components that can only be shipped to specified countries as a result of shipping route and speed of delivery. The approach is also controlled by the customers who prefer shipping from specific locations as the customers are paying for the shipping cost if they are shipping from those ports. Such arrangements are

primarily due to the shippers available in each area and the ease of passing through the custom. Table 7 below is the breakdown of the distribution. For example, Plant P1 will supply component 5 to Greater China and India, while Plant P5 will supply component 5 to Korea, SEA and Japan.

Production Plant	Component Supplies	Country
P1	5	Greater China
		India
	6	Greater China
		India
		Korea
P4	2	Greater China
		India
		Japan
		Korea
		SEA
P5	5	Korea
		SEA
		Japan
	6	SEA
		Japan
P7	1	Greater China
		India
		Japan
		Korea
		SEA

Table 7: Production Plant, Component Supplies and Country Mapping

Given the need to handle intermittent demands, the various production plants have different inventory storage limits and different cost for storing their inventory. The cost of inventory fluctuates as a result of local electricity and maintenance fees as the components are held in specialised warehouses. The tropical heat and humidity in the region can cause serious damage to the components through mildew and rust. The special facility maintains constant and optimal storage conditions for these components. Table 8 and 9 below showcase the breakdown of the inventory volume limits and unit inventory holding costs for the next 12 months in 2012 at the different production plant.

Plant Location	P1	P4	P5	P7
201201	1421140	4263420	1470016	1541585
201202	1421140	4263420	1470016	1541585
201203	1744869	5234607	1650877	1744492

201204	1744869	5234607	1650877	1744492
201205	1744745	5234235	1624015	1780055
201206	1744745	5234235	1624015	1780055
201207	1791077	5373231	1270015	1664717
201208	1791077	5373231	1270015	1664717
201209	1463540	4390620	1479964	1471949
201210	1463540	4390620	1479964	1471949
201211	1651848	4955544	1557211	1454079
201212	1651848	4955544	1557211	1454079

Table 8: Inventory Volume Limits for 2012 at Different Plants

Plant Location	P1	P4	P5	P7
201201	$0.50	$0.40	$0.30	$0.10
201202	$0.40	$0.10	$0.30	$0.20
201203	$0.50	$0.10	$0.10	$0.20
201204	$0.20	$0.10	$0.30	$0.50
201205	$0.20	$0.40	$0.20	$0.30
201206	$0.10	$0.50	$0.10	$0.10
201207	$0.50	$0.20	$0.50	$0.30
201208	$0.20	$0.50	$0.20	$0.30
201209	$0.30	$0.10	$0.20	$0.20
201210	$0.50	$0.50	$0.50	$0.40
201211	$0.50	$0.10	$0.20	$0.10
201212	$0.20	$0.30	$0.10	$0.20

Table 9: Unit Inventory Holding Costs for 2012 at Different Plants

The supply chain process flow is a complex one. Figure 1 depicts how the different plants produce the components, and each component is used in different products, and the different products are consumed in different countries, which are markets for the different customers.

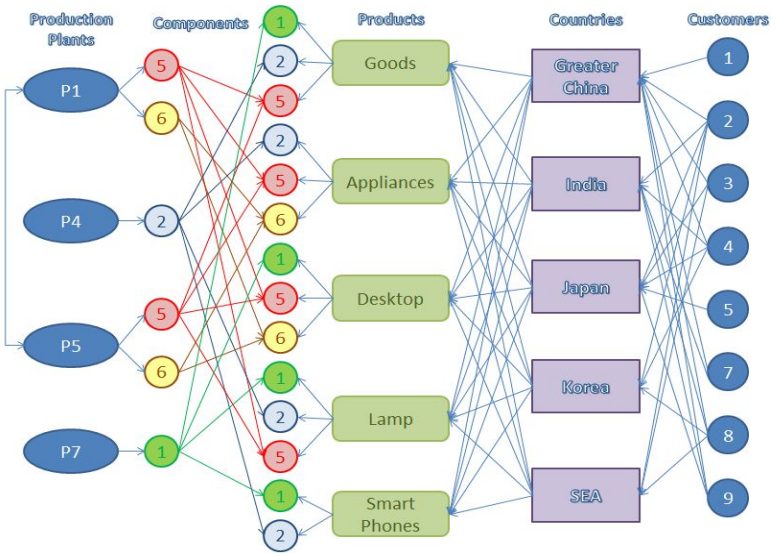

Figure 1 – Supply Chain Network

4 THE BUSINESS PROBLEM

In light of recent competitive developments, the executive management team in Advance Cable Manufacturing Sdn. Bhd. have placed greater emphasis on managing their production planning and inventory performance. The purpose and shift in focus are primarily driven by the need to reduce cost and efficient delivery of goods to market. To achieve the goals, the team would like to begin by producing a comprehensive supply chain plan for the next 12 months based on their demand forecasts, production capacity, shipping capacity and expected costs. The plan is supported by data and decision science models which guides the management's decision-making process.

Advance Cable Manufacturing Sdn. Bhd. invites you, the decision science expert, to assist the executive management team by producing the necessary supply chain plans for the next 12 months based on the past 2 years' monthly sales volume. The plan has to be supported and driven by data. The plan has to be compelling with innovative approaches providing sound projections for 2012. Due to the lack of experience in the area of decision science, the methodology provided requires clear and simple explanations to ensure the management team's understanding. Clear references to other case studies and implementations are encouraged especially when they provide clear benefits for the plan.

As a decision science expert, you are excited about the opportunity was given to solve the real-world business problem. However, you are also sceptical about solving it within the short time frame given as it covers the whole process of forecasting, production planning and inventory controls. You are optimistic that if you can talk to the people on the ground and analyse the data, it shouldn't be any different from other projects that you have undertaken before. With these ideas in mind, you now have the confidence to take up the challenges and the journey has just begun.

Teaching Guide

SYNOPSIS OF THE CASE

The case study requires the application of forecasting models, inventory management and assignment approaches to solving the case. Due to the complexities involved, it will be difficult for the undergraduates for any decision science subjects to tackle the problem in a single setting. It is recommended that the instructor using the case study to break the case across multiple lessons and solving a specific aspect of the problem in each class. Graduate students will be well suited to tackle the case due to advanced knowledge and practitioner experience in decision science subjects.

TARGET GROUP

Undergraduate or graduate students pursuing a degree in any decision science subjects. Students must have prior experience with Excel, R or any forecasting software. It is imperative that the students have exposure to forecasting techniques, mixed-integer linear programming or integer programming. Students should have some basic understanding of the manufacturing industry, shipping industry, logistics and lean manufacturing. In the case of undergraduate coursework, we recommend the case study to be used in level 3000 or 4000 modules.

PEDAGOGICAL OBJECTIVES

This case study's main objectives are to help students in the following:

- Understand the management's perspective and the business environment that can affect the approach to solve the problem using decision science.
- Discuss the problem statement and identify relevant inputs and required outputs
- Learn to build models to tackle business problems with minimal prior industry knowledge
- To inculcate an appreciation of forecasting techniques and how the forecasts have an impact on the subsequent business decisions and the knock-on effects on supply chain

planning.
- To appreciate the relationship between production assignment problems, inventory holding issues and delivery logistics problem.
- Develop an appreciation for the complexities of supply chain issues in real life.
- Develop the skills and confidence to apply forecasting and optimisation techniques to solve a business problem
- Analyze and solve real-world business problems using the Excel optimisation tools.

CASE ANALYSIS

The analysis of the problem in this case study starts with an understanding of the problem and making appropriate assumptions. After initial "brainstorming", students should be able to list the key inputs of the models and the necessary outputs at each stage of the plan that acts as the inputs to the next model.

The instructor should begin the case by introducing the following concepts to the students:

- Manufacturing business models
- Difficulties in securing raw material supplies
- Logistics of manufacturing industry
- Managing inventory in manufacturing
- The management of cost in manufacturing

There are 3 main discussion questions.
1. How should we tackle the problem?
2. What are the techniques that we can use to solve the problem?
3. Are there other business considerations?

Specific topics discussion questions.

Forecasting

- What are the popular techniques for forecasting?
- Do you foresee issues with the small amount of data for forecasting?
- Given the need to present the forecasts to senior management who are more comfortable with Excel spreadsheets, do you think using a simpler model that is available in Excel spreadsheet will be more readily accepted?
- Do you think advanced forecasting techniques such as neural network will work well in this case?
- Would Croston's method work as well in this case?
- What are the suitable measures to determine the best forecasting model?

Inventory Management

- How do you relate the inventory holding costs to the concept of lean manufacturing?
- Do you think that holding inventories in cheaper countries will facilitate lean manufacturing?
- What would be the best inventory holding condition and does that affect your shipping and manufacturing model?

Manufacturing Assignment

- Besides Mixed Integer Linear Programming (**MILP**), what other assignment techniques can be applied?

Logistics and Shipping

- If there are intermediate shipping locations which can store the inventories at a very cheap rate, how does that affect the shipping problem?

Main objectives of this case require the students to make bold assumptions, explore uncertainty and model ambiguous and ill-defined business problem. The model can help students to deal with reality and uncertainties of real business and develop the managerial judgment to develop an optimal solution.

Forecasting Problem Teaching Guide

Forecasting Model

Before we begin to perform forecasting, the preceding discussion should list all the necessary business constraints and information. The main data that we will be using to build our forecasting model is the sales training data sheet. The data contains the previous order volume from the various customers needed in the specific region. The data contains many zeroes as the order volume from various clients are inconsistent which is a major problem in real-world forecasting situation.

At this point, it may not be clear to students why the zeroes are a major obstacle to forecasting. It is important for the instructor to highlight the excessive zeroes are an indication of a type of phenomenon called **intermittent demand** problem. To tackle these problems, the students will need to learn Croston's method. However, in the interest of time and simplicity, those demand data with excessive zeroes will be forecasted using the mean value of actual demand (non-zero data points). In the case of a client who has not ordered in years, we may assume that there will be no future orders.

We will demonstrate an approach to solve the forecasting problem in R using auto.arima function below. Before the students begin this exercise, they have to make a copy of the file on their own Google drive.

```
#########################################################################
#####Step by step guide to solving the forecasting section of the problem.
#########################################################################
if(!"googlesheets" %in% rownames(installed.packages()) | !"forecast" %in%
rownames(installed.packages())){
  install.packages(c("googlesheets","forecast"))
}
###Loading the necessary library
library(googlesheets)
library(forecast)
#########################################################################
```

Snippet 1: R packages checking and installation

Before we begin the process of forecasting, we must first install the relevant packages in the R software that will enable us to perform the necessary tasks. To perform automated forecasting, we will need the R package "forecast" which contains the auto.arima function that does automated time series modelling. By using this approach, the instructor can progress faster without having to go through the details of ARIMA forecasting. To enable access to the data that is stored on Google drive, we will be using the "googlesheets" R package to retrieve and return data to Google Sheets.

```
###Importing the data for forecasting
##This function requires you to authenticate with Google Sheets in order
##to list the various sheets available for you to analyse.
gs_ls()
#The data that we will be interested in is the Sales Training data
sales.train.data <- gs_title("Sales Training Data")
#To get the right data, we can use the list worksheets function to review
#the sheets available within each workbook.
gs_ws_ls(sales.train.data)
#There are 2 sheets: "Sales Training Data" and "Test Data"
#The Sales Data is in "Sales Training Data" sheet and we are reading that.
sales.train.data.model <- gs_read(ss=sales.train.data, ws = "Sales Training
Data")
# Converting the data into a proper data.frame
sales.train.data.model <- as.data.frame(sales.train.data.model)
#The test Data is in "Sales Test Data" sheet and we are reading that.
sales.test.data.model <- gs_read(ss=sales.train.data, ws = "Test Data")
#Converting the data into a proper data.frame
sales.test.data.model <- as.data.frame(sales.test.data.model)
#Create the forecast dataset
sales.forecast.data.model<-sales.test.data.model
##############################################################################
```

Snippet 2: Data extraction from Google Sheet

Once the packages are installed, we can then begin the process of extracting the relevant information from the sales data that is stored on Google drive as a Google sheet. Below is a screenshot of the Google sheet containing the sales information.

	A	B	C	D
1	TimeData	nt_1_Greater_C	nt_2_Greater_C	Client_2_India
2	01/01/2010	2497119	480678	0
3	02/01/2010	1340453	375365	26100
4	03/01/2010	1528156	522655	13050
5	04/01/2010	1666921	788874	26100
6	05/01/2010	1838964	629884	8700
7	06/01/2010	1762838	930466	13050
8	07/01/2010	2189791	709269	0
9	08/01/2010	1927356	693176	27840

Figure 2: Sales training data in Google sheet on Google drive

We will first connect to Google drive using the R package and list the files. The file should be named “Sales Training Data”. There are two sheets, the first one is the training data while the second one is the test data (Actual data). After connecting to the sheets, we will convert the information in Google sheet into R data frames which will be used for building forecasting models.

```
#At this point, depending on the approach taken by the instructor, the
#material presented here can vary due to the forecasting approach. In
#this particular case, we will be using auto.arima approach solve the
#problem.

#This step extracts all the clients and regions combination from the data
listofregionsclients<-names(sales.train.data.model)[2:ncol(sales.train.data.mod
el)]

#We will iterate through the regions and use the automated forecasting
#approach to predict the model.
#Depending on the skill levels of the students, you can choose to run
#Seasonal models and non seasonal models too

for (i in 1:length(listofregionsclients)){
  ##Giving you an indication of the process
  print(i)
  ###Preparing the data in the appropriate time series structure
  model.data.train.sample<-ts(sales.train.data.model[listofregionsclients[i]],
  start=c(2010,1),frequency=12)
  ###The ARIMA model is selected with both seasonal differencing and first
  order differencing
  model.Arima <- auto.arima(model.data.train.sample,d=1,D=1)
  ###Forecasting the future
  model.result<-forecast(model.Arima,h=12)
  ###Storing the results
```

```
  sales.forecast.data.model[listofregionsclients[i]]<-as.numeric(model.result$
  mean)
}

###Uploading the data for review
sales.train.data %>% gs_ws_new(ws_title = "forecast results", input =
sales.forecast.data.model,trim = TRUE, verbose = FALSE)
##############################################################################
```

Snippet 3: Data preparation and automated forecasting.

Once the data has been offloaded into R as dataframes, we will then proceed to build the forecasting model. It is important that the instructor explains the choice of approach and model. In this particular case where ARIMA is used, there are two strong reasons to support its adoption.

The first reason is the ease of understanding. It is recognised that there are more powerful models such as neural networks or X-11 are available for use. However, the management team is new to the approach and is unlikely to be quantitatively oriented nor technically skilled to comprehend these models. Through ARIMA models, most of the models can be simplified in autoregression terms or moving average terms. The simplicity will likely to ease the discomfort of the management.

The second issue that will likely to escape the students' thought process is the problem of implementation. Again, the auto.arima function provides a simpler and faster approach to update the forecasting model as compared to other approaches. Re-running more advanced models such as neural network or Deep learning will likely to consume more time and resources. Updating those models will also involve a degree of human interaction which can be avoided in the case of auto.arima.

Once the models have been built and forecasts are generated, we will push the data back into the Google sheet on a new sheet. The Google sheet provides us with the ability to examine the forecasts in greater details. Students are reminded to understand the model assumptions such that a forecast is based on historical trend and not drastically change over time. A good forecasting model is important but we also need to be aware that we could never develop a 100% accurate forecast model.

Optimisation Problem Teaching Guide

Optimisation Model

Before the instructor proceeds with the optimisation model, it is important to discuss the forecasts and the actual results to understand the gaps. At this point in time, it is good for the instructor to point out that customers can actually return goods due to a lack of demand or as a result of contractual terms. This is reflected by the negative number in the demand table. Due to a large number of constraints present in the optimisation problem, most versions of Excel solvers will not be able to tackle the problem. We recommend the use of LibreOffice solver add-on or the use of Google sheet solvers in the event that the instructor will like the student the problem without exploiting the underlying data structure simplification process. At the later stage of the problem formulation, we will exploit the structure of the problem to render it solvable using Excel Solver.

As we start the optimisation process, it is important for us to identify the various inputs and outputs required by the model. There are several dimensions to this problem. To simplify the process for the students, we will describe the variables in greater details and how they are relevant to the problem.

Unlike most of the formulation where they first start with the inputs or outputs, we will begin with the critical dimensions that form the subscripts of the key variables. It is important to define time. The time period as represented by t in this problem is on a monthly basis and all production or transhipment will take a month to complete. There are four plants around the region and they are represented as p. The components are represented as c. The final goods/materials are represented by m

Variable	**Symbol**
Time	t
Plant	p
Component	c
Materials	m

Geography	g
Client	l
Component-Material Ratio	r

Table 10: Dimension variables and the respective symbols

The output variables will be the demand and cost of production which includes manufacturing cost, storage cost and transhipment cost. The output variables are important as they form the target objective and constraints that have to be achieved. In most optimisation problems, the cost variables will form the objective function.

Input Parameter	**Symbol**
Production Cost	E
Transhipment Cost	F
Inventory Cost	G

Table 11: Output variables and the respective symbols

The input variables for this problem are the amount of component to be produced, the amount of components to hold in order to meet the demand and transhipment among the plants. The decision variables will be the solution to the supply chain problem as they will provide the required solution.

Decision Variable	**Symbol**
Production	A
Inventory	B
Demand	D
Transhipment In	I
Transhipment Out	O

Table 12: Input variables and the respective symbols

The limit parameters are the constraints or limits of reality that has to be achieved.

Input Parameter on Limit	**Symbol**
Production Limit	L

Transhipment Limit	Q
Inventory Limit	W

Table 13: Limit variables and the respective symbols

The first step to solve the problem is to identify the number of components required by the clients in various regions. To compute this, we must first formulate the breakdown of the materials into the components. Mathematically, this can be formulated as the following.

$$D_{c,t,g,l} = \sum_{m} r_{m,c} D_{m,t,g,l} \quad \text{- (1)}$$

Equation 1 represents the breakdown of the demand for goods for a specific client in a geography for a time period into the demand for the component. Once we have the demand for the components, we will need to evaluate the production of components to meet the demand. In this formulation, we have to identify a number of items that will have an impact on the business problem. To meet the demand, it is possible to produce more and then hold on to the excess as inventory that can be used for the next period. When it is not possible to achieve that, the problem can be solved through transhipment of goods from other production facilities. At this point, students should be probed with regards to oversupplies at the plants to meet the future demand, what do we do with the produced goods? Concepts of inventory management, warehouse capacity and holding cost will be discussed. Taking those into consideration, the formulation is as below.

$$A_{c,t,g,p} + B_{c,t-1,g,l} - B_{c,t,g,p} + I_{c,t,g,p} - O_{c,t,g,p} = D_{c,t,g,l} \quad \text{- (2)}$$

Equation 2 represents the production of components to meet of the demand for goods for a specific client in a geography for a time period. Given that we have the production constraints, we now need to set the limits of the constraints.

$$\sum_{c}\sum_{g} A_{c,t,g,p} \le L_{t,p} \quad \text{- (3)}$$

$$\sum_{c}\sum_{g} \left(B_{c,t,g,p} - B_{c,t-1,g,p} \right) \le W_{t,p} \quad \text{- (4)}$$

$$\sum_{c}\sum_{g} \left(I_{c,t,g,p} + O_{c,t,g,p} \right) \le Q_{t,p} \quad \text{- (5)}$$

Equations 3, 4 and 5 represents the various production limits, transhipment limits and inventory holding limits respectively. On top of the constraints, we will also need to establish some relationships between the transhipment variables. Given that the transhipments can only occur between specific plants, we need to set up specific relationship equations.

$$I_{c,t,g,p} = O_{c,t-1,g,p} \quad \text{- (6)}$$

$A_{c,t,g,p} \ge 0$ and are integers - (7)

$$B_{c,t,g,p} \geq 0 \quad \text{and are integers} \quad \text{- (8)}$$

$$I_{c,t,g,p} \geq 0 \quad \text{and are integers} \quad \text{- (9)}$$

$$O_{c,t,g,p} \geq 0 \quad \text{and are integers} \quad \text{- (10)}$$

Equation 6 forces the model to only consider valid transhipment relationships as described in the business case. Equations 7, 8, 9 and 10 forces the values to be positive integer values. Once we have all the constraints, we can now set up the objective function which will guide the optimisation process.

$$Cost = min\ w.r.t \sum_c \sum_t \sum_g \sum_p \left(E_{c,t,g,p} A_{c,t,g,p} + G_{c,t,g,p} B_{c,t,g,p} + F_{c,t,g,p} I_{c,t,g,p} \right) \quad \text{- (11)}$$

At this point in time, it will be useful for the instructor to highlight an interesting observation with regard to the kind of component that can be produced. Component 5 and 6 are only produced at Plant P1 and P5. Component 1 and 2 are only produced at specific plants that can be shipped to all markets. By exploiting this unique property, the solution to this problem can be assembled by solving three simpler problems.

1. Component 1 supply chain optimisation
2. Component 2 supply chain optimisation
3. Components 5 and 6 supply chain optimisation

Instructors are advised to utilise this opportunity to explain to students the importance of exploiting business problem and data structure to simplify the optimisation formulation process. At this juncture, it is important to impress upon the students the advantages of problem simplification and how it can reduce the resource needed to solve the problem. Instructors who would like to demonstrate the difference can request the students to attempt both approaches to solving the problem. Most students will encounter difficulties with Excel's inbuilt solver to solve the problem.

Students are required to follow the steps and compute all the components required for all the customers in various location. The Instructor may use the Excel solution workbooks to guide the students.

ABSTRACT

Manpower planning is central to most business because human resources are scarce and expensive. We wrote our consultancy project into a case study for classroom teaching, in order to bring some realism into the classroom. It is important for students to learn problem solving and analytical skillsets in a real-world context. Using the case, we show how students can analyze historical data to derive insights and construct a useful basic model developed from scratch, and thereafter, enhancing it to include more complexities. The model thus produced can directly applied to improve staff productivity.

KEYWORDS:—manpower planning, Utilisation, Sensitivity analysis, Linear relationship, Optimal resource

INTRODUCTION

Our client ABC is a service company whose customers would submit their applications online before a deadline for some premium services. The company would only shortlist certain applicants according to their business rules as their services were always oversubscribed. Customers would be notified via email if they were chosen. They would also be given an appointment date to come and meet with the customer service officer (CSO) and select from some premium services (S1, S2 and S3). If the customer could not attend the scheduled appointment, they would reschedule with the company to the next available timeslot. Figure 1 shows the business process of servicing the customer.

Figure 1: Business process of servicing the customer

Our problem will focus on stage 3 and 4 of the business process.

Stage 3: (Manpower planning) The manager needs to determine how many appointments a CSO can clear per month and how long will it take to service all the shortlisted applicants. The current process has the manager doing this assignment based on his "gut" feelings and personal experience. The current practice is for each customer to be given X minutes at the counter regardless of the service that they will choose and each CSO is assigned Y customers based on their utilization rate and daily working hour. Staff utilization rate is defined as the total amount of time spent to service the customer divided by the total capacity. Some CSOs complain that they are unable to service all the customers within the working hour and they are working overtime without pay. The workload distribution among staff is also uneven even though the manager thinks that it is a fair assignment as every staff is given the same number of customers to serve.

Stage 4: (Service customers) On the appointment date, there are instances where the shortlisted applicants do not show up (No show). In this case, the company loses its revenue and wastes its manpower resources as the CSO has already been allocated. On the other hand, if the customer shows up, the CSO opens the appointment file and registers the start time of appointment. The CSO services the customer based on their selection of services type (S1, S2 or S3). Once the service is done, end of service time is recorded and they proceed to the serve the next customers in line. The company also collects service time statistics and customer's feedback through survey at the end of stage 4.

Recently, there have been numerous complaints by the customers that the lead time from shortlisting to seeing the CSO is very long; in some cases, the appointment date is scheduled more than 30 days after shortlisting. The service level agreement (SLA) states that the company will serve all the customers within 30 days from shortlisting; otherwise there is a service failure on their part and the company's reputation can be jeopardized. The management of the company is interested to know whether or not the complaints are legitimate, and if so what do they need to do provide better service to the customers.

Manpower planning goes beyond day to day scheduling and operation. It also involves macro level planning (timeframes from 3-6 months) such as budgeting for new hire and headcounts. New staff needs training to become proficient thus management need to know well ahead of time how many more staff will be required to meet the SLA.

Time has changed, and customer centricity should be in the heard of organization culture. Customer expects high quality and customized/personalized service from the company to stay loyal. There are a lot of data being collected within the company. The data ranges from customers' demographics to the appointment details. It is vital for the company to embark on data analytics and provide valuable insights into service performance related to SLA and staff utilization rate.

This case study's main objectives are to help students in the following:

- Explain the importance of managing people within the organization

- Analyze the past historical data to get insights about the current situation
- Explain the importance of macro level manpower planning within the organization
- Develop the manpower planning model from scratch and enhance it to solve company manpower issues

- Illustrate the importance of manpower planning to fulfill customers need
- Implement sensitivity analysis on a spreadsheet model to emulate various business scenarios

(Dantzig, 1954) first introduced Integer programming (IP) model to solve the shift scheduling problem at the toll booths. IP assumes that all the decision variables are only take integer values. The second variation is where all the decision variables are binary (either 0 or 1), then it is called binary integer model. The third type is a mixed integer programming model (MIP) where there is a mixed of integers and non-integers value which are stated in (Anderson, Sweeney, Williams, & Martin, 2012).

Generally, most scheduling problems are NP-hard which means that we are not able to find the solution within polynomial-time. However, due to the business requirement to get the solutions within a short time frame, these problems are solved using business rules, logic or heuristics approach. The following researchers have worked on various versions of resource scheduling problem in over the years, (Ozcan, 2005), (Cezik, Gunluk and Luss, 2001), and (Bard, Jarrah and deSilva, 1994) solved the employees requirement probmem for each period of the day using IP and the objective is to minimize the manpower cost using forecasted demand for labours. (Al-Yakoob, S.M & Sherali, 2007) used mixed-integer programming model to schedule the employee working multiple shifts and over 86 stations distributed all over Kuwait.

(Barker, 2015) focused on developing real-world optimization model using Spreadsheets. (Ma, Choy and Sen, 2014), solved a similar problem which is related to planning for check-in counter resources at the airport. The authors developed a predictive model using historical data such as airline code, destination, region, day of week, month of they year to determine the forecasted passenger load. Using the forecasted passenger load, the authors developed a simulation model to where it seeks to determine an optimal number of check-in-counters at the airport to service a predicted passenger load within the service level agreements. The study used a six step methodology to solve passenger load and check-in counter requirement problems. The developed simulation model enables the terminal manager to visualize how various input parameters such as passenger loads impact the number of counters required and the resulting service level performance. This methodology can be adapted for the current problem statement, where past historical data can be analyzed and derived the input parameter such as service time and staff utilization rate for the mathematical model.

Macro level human resource planning focus on planning timeframes of 3 months to 6 months rather than daily operation. It is beneficial for organization to forecast the number of skilled

manpower required based on forecasted customer's demand to ensure business-as usual, efficient, smooth operations on a daily basis, by identifying manpower gaps and allowing lead time for training of these skilled labour. It also allows organization to forecast financial requirements such as budgeting for headcount (Prasad, 2012).

We need to build a customized model for manpower planning using spreadsheet as the business problem is quite unique to the organization in this study and they are not willing to purchase any commercial software for this purpose. They are also building up their analytics capability within the organization so they want us to impart and share our knowledge to develop this system. Spreadsheet is chosen as it is cheap and widely available within the organization. It is also easy to use and doesn't require any additional training. Therefore, we will start our discussion with the understanding of the business problem and try to identify any bottleneck from the data. A mathematical model will be built using the input from data to solve the macro level manpower planning issue.

In the next few sections, we analyze the historical data available and aim to derive input parameters for manpower planning. Subsequently, we develop a mathematical model for this purpose and run multiple business scenarios which comprises of changing the number of shortlisted applicants verses number of staff and the staff utilization rate. We share how this course has been delivered to thousands of undergraduate students annually in our university. We also highlight the challenges faced when teaching this kind of course to students and how we are able to adopt it into the successful delivery of the course. Finally, we discuss some learning points from the model and future work with a conclusion.

CASE ANALYSIS

Problem description

Students are asked to identify what is the problem they are trying to solve in this case? Two datasets were given to students which include fifteen months of historical data with tens of thousands of shortlisted applicants' detail. "CustomerDB" includes customer demographic information such as Customer ID, Age Group, Income Level, Gender, etc. The second dataset namely "AppointmentDB" comprises of Customer ID, Shortlisted Date, Staff ID, Date and Time of appointments, Status of appointment (Show, No Show), Type of service chosen (S1, S2, S3) and service start and end time.

We want students to learn how to ask the right questions to answer the business problem. This part is quite hard for them as they have no or litter experiences working in the industry. The discussion focus on customer complaints of service failure; and what they think is the main issue. Most students will say it is due to no enough CSOs to service the customer. How do they know it is the case? They are reminded that any claim needs to be supported by data, and

hopeful they will grow accustomed to this process of data to decision making. Can they build a mathematical model to answer the followings?

a. The first business problem is to derive the amount of time required to service all the shortlisted applicants using a given/fixed number of CSOs available.
b. Is the current strength of CSOs enough to meet the SLA?
c. What will be the optimal numbers of staff required for their daily operation?

Currently, human resource planning is done manually based on the manager's personal experience. Thus, it is difficult to accurately estimate the total amount of time required based on the appointments. The estimate of number of appointment multiply by X minute is a poor estimate of the actual time required. Therefore, this becomes our objective in this study, to gather the right service time and parameter and develop a useful macro level manpower planning tool to assist us in decision-making process. It is important for the company to manage its manpower resource effectively to achieve organizational goals, i.e. optimizing manpower resources and reducing the amount of time required to clear the shortlisted applicants. Understanding the resource utilization also allows the organization to benchmark its productivity rates within the same or across various industries.

Data input and preparation

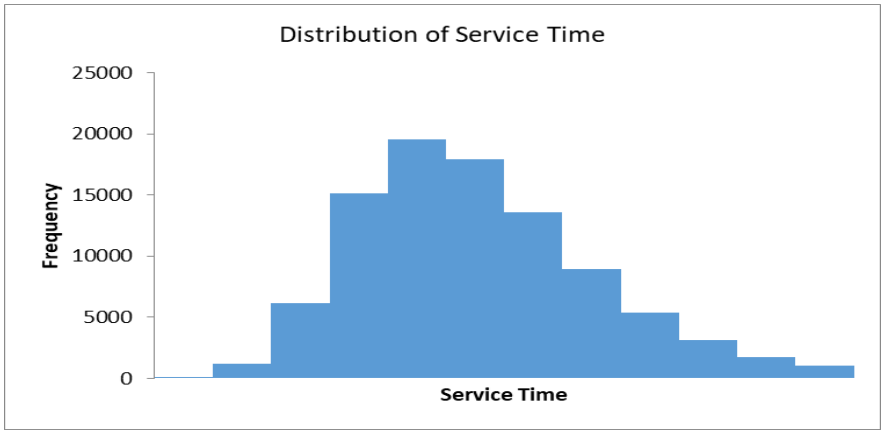
Before creating the spreadsheet model, the preceding open-ended discussion is concluded with the class collectively listing variables relevant to the model. Students need to merge two datasets into one common dataset using Customer ID. Students are required to share interesting insights after analyzing the data.

There is a large disparity in the service time between different age group and various service type. There is a consistent proportion of age group who apply each month and this information is used in our model. Twenty percent (20%) of the applicants who are shortlisted do not show up for the appointment. The company's plan is to develop a data mining model to predict the status of appointment but this is beyond the scope of this case.

From "appointmentDB", we need to derive a new field called service time which is the difference between the service end time and service start time. We can also compute the total time take by each staff to service the customer, hence the average utilization rate of each staff can be computed. Staff utilization rate also varies between 50% to 85%. For simplicity, we take an average utilization rate for all CSOs. Students are asked to explore what other parameters they think management might be interested. Since most customers complained about long lead time, the data can help them to answer what has happened. How many percent % of the shortlisted applicants have a lead time of more than 30 days? We can also compute the lead time from the shortlisted date to the appointment date, the waiting time for each appointment which is the maximum of 0 or (Appointment start time – schedule time).

The customers are grouped into various age groups based on their customer demographic information, A1 represents the young, A2 represents the middle-aged and A3 represents the elderly. 70% of the population belongs to A1, 20% of A2 and the remaining 10% is A3. We have a total of nine categories summarizing the distribution of the service time for each customer age group and service type (A1 S1, A1 S2 … etc). (Figure 2) below is an example of service time for A1 S1. It was observed that the distribution of the service time for all group is normally distributed and we use the mean as the average service time. We also remove the outliers which are +/- 3 times the value of standard deviation.

Figure 2: Distribution of service time for A1 S1



Without loss of generality, we have summarized the proportion of shortlisted appointment by age group (A1, A2, and A3), service type (S1, S2, and S3) and their respective service time in Table 1. A customer, whose age group is A1 and required service S1 will need 0.1 hours which is about 6 minutes. The variation of service time also differ tremendously among various age group for the same service type. Without the support of data analysis, the manager does not realize that it may cause a big issue in the customer waiting time, service quality, and staff productivity. Two staff may be serving the same number of customers each day but their utilization can be very different, e.g. A3 S1 needs 4 times longer than A1 S1.

Table 1: Customers by age group and service time

	Service time	**S1**	**S2**	**S3**
	Total shortlisted applicants	**Hours**	**Hours**	**Hours**
Age Group	A1	0.1	0.15	0.2
	A2	0.3	0.4	0.45
	A3	0.4	0.45	0.5

Table 2 shows the percentage of service selected by each age group**.** For age group A1, the proportion of services required also varies, 20% of A1 selected S1, 30% of A1 chose S2 and the remaining 50% required S3 service.

Table 2: Percentages of service selected by each age group

Service Selected	S1	S2	S3
A1 (70%)	20%	30%	50%
A2 (20%)	30%	30%	40%
A3 (10%)	10%	40%	50%

The working hour per employee is 8 hours daily, and they are multi-tasking. There are 5 staff available. Our model assumes that there are 22 working days in a month as they need to work 5.5 days including a Saturday half day, but they should not be 100% utilized to be realistic thus the model needs to capture this operational constraint. They only spend a proportion of their time to service the customer; because at other times they are also needed to support other business operations like preparing the quote and liaising with various vendors. Staff utilization rate denotes the percentage of time an employee will spend on serving the customers. The following Table 3 shows the input.

Table 3: Staff parameters and past 15 month's shortlisted number of applicants

Staff	5
Working hours	8.0
Utilization rate	60%
Time period (Month)	**Total shortlist applicants**
1	2300
2	1897
3	3254
4	2056
5	1692
6	4586
7	1298
8	3490
9	2876
10	3987
11	3456
12	5348
13	3546
14	5498
15	3450

Business Questions for the case

Question 1:
Assuming that there is a fixed number CSOs available daily, the management would like to know how fast can we service all the customers with the current number of resources? How many man days/man months will be required to service the total number of shortlisted applicants? Run the sensitivity analysis by varying the staff utilization rate from 60%-80. How does it affect the total duration? A service failure occurs when the total duration of service is 10% more than the total man day in a month. How many months does the service failure happen?
If the management would like to service all the shortlisted applicants within the same month, how many employees do they need each month?

Question 2:
If we need to suggest any changes to the plan in future, what is the optimal number of staff the company needs to hire to avoid service failure? ? If we vary the number of shortlisted applicants by +/- 20%, what is the impact on the manpower requirement?

CASES DEVELOPMENT/MODEL BUILDING

Model 1: Manpower planning model

Before we build the first model, we discuss the influence diagram shown in Figure 3, what are the input, output and how they are linked together using influence diagram. We can also visualize the number of shortlisted applicants over 15 months using a bar-chart in Figure 4. We can see that the number of shortlisted applicants over the 15 months fluctuates a lot with the highest number of shortlisted applicants on month 14th with 5498; which is 1.7 times of the average number of shortlisted applicants per month (average = 3249). From this graph, we should already anticipate there will be some resource issues. The macro-level resource planning will look at the overall service quality and failure over a period of 3 months to 1 year.

Figure 3: Influence diagram to compute total man days

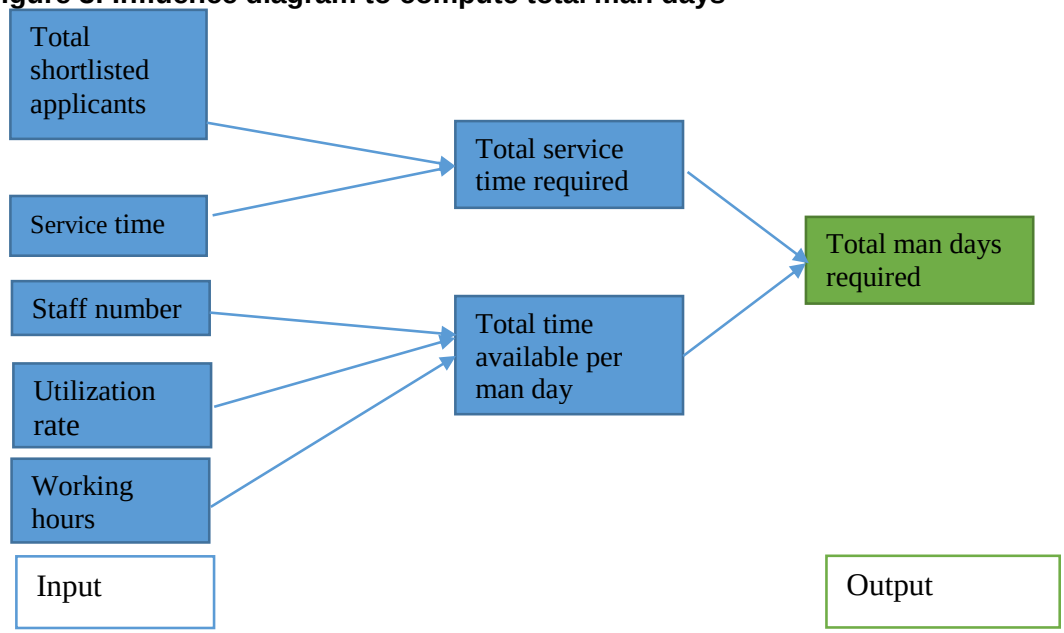


Figure 4: Total shortlisted applicants over time

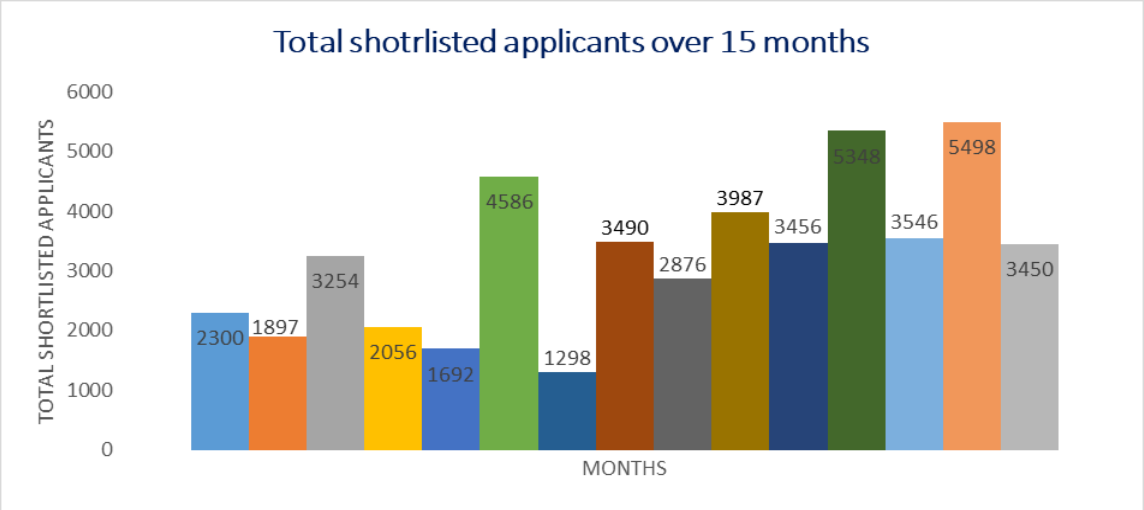

We need to compute the shortlisted applicants by age group A1, A2 and A3 and compute the total time required for each age (T_A1, T_A2, T_A3) group accordingly to percentages of required service (i.e. various service time S1, S2 and S3). We can sum up T_A1, T_A2 and T_A3 to get the total time required (T_1) to service all the shortlisted applicants. We also need to compute the total available time per day using number of staff, utilization rate and working hours.

Let number of CSO available be C
Total A1 = Total shortlisted applicants * 70%
Total A2 = Total shortlisted applicants * 20%
Total A3 = Total shortlisted applicants * 10%
Total time required by A1 (T_A1) = Total A1 (20% * S1 + 30% * S2 + 50% * S3)
Total time required by A2 (T_A2) = Total A2 (30% * S1 + 30% * S2 + 40% * S3)
Total time required by A3 (T_A3) = Total A3 (10% * S1 + 40% * S2 + 50% * S3)
Total time required (T_1) = T_A1 + T_A2 + T_A3
Total time available per man day (T_2) = C * utilization rate * working hour
Total man days required = Total time required (T_1) / total time available per man day (T_2)
We can easily convert number of man days to man month by dividing it by 22. We can compute if there is a service failure in each month using IF formula. The excel template (
Figure 5) below shows the solution for model 1. The number of months when the service failure happens is actually quite high, which is **2 out of 3** of the total. We also use conditional formatting in Excel to highlight those months which had a service failure (i.e. # of man month > 1.1).

The conclusive remark after developing this model is the percentage of service failure over 15 months is more than 60% and it can help to answer how many man months will be required based on current staff number. The current number of CSOs deployed is not enough to service all the number of shortlisted applicants per month.

Figure 5: Excel solution for Model 1 - To compute number of man days

		Number of applicants			Total time required					Service failure	1.1	
Time period (Months)	Shortlisted Applicants	Total A1	Total A2	Total A3	T_A1	T_A2	T_A3	Total time required (T_1)	# of days	Convert to month	Service Failure	Number of staff required
1	2300	1610	460	230	265.7	179.4	108.1	553.2	23.05	1.05	N	6
2	1897	1328	379	190	219.1	148.0	89.2	456.2	19.01	0.86	N	5

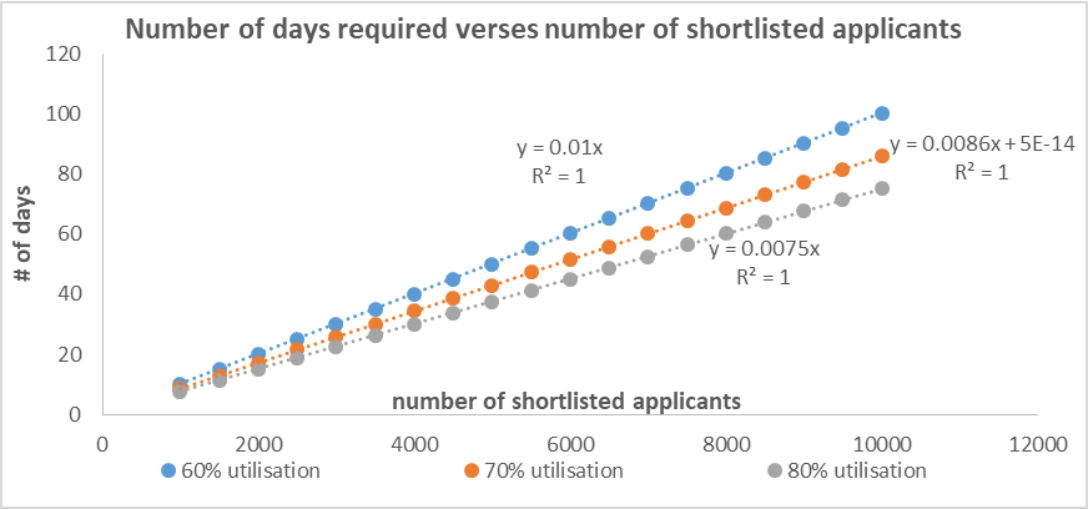
4	2056	1439	411	206	237.5	160.4	96.6	494.5	20.60	0.94	N	5
5	1692	1184	338	169	195.4	132.0	79.5	406.9	16.96	0.77	N	4
6	4586	3210	917	459	529.7	357.7	215.5	1102.9	45.96	2.09	Y	11
7	1298	909	260	130	149.9	101.2	61.0	312.2	13.01	0.59	N	3
8	3490	2443	698	349	403.1	272.2	164.0	839.3	34.97	1.59	Y	8
9	2876	2013	575	288	332.2	224.3	135.2	691.7	28.82	1.31	Y	7
10	3987	2791	797	399	460.5	311.0	187.4	958.9	39.95	1.82	Y	10
11	3456	2419	691	346	399.2	269.6	162.4	831.2	34.63	1.57	Y	8
12	5348	3744	1070	535	617.7	417.1	251.4	1286.2	53.59	2.44	Y	13
13	3546	2482	709	355	409.6	276.6	166.7	852.8	35.53	1.62	Y	9
14	5498	3849	1100	550	635.0	428.8	258.4	1322.3	55.09	2.50	Y	13
15	3450	2415	690	345	398.5	269.1	162.2	829.7	34.57	1.57	Y	8

We can run sensitivity analysis by changing the staff utilization rate between 60% - 80%, which will affect the total available time per day and we can plot the graph to show the relationship between the total shortlisted applicant and the number # of man days required. As we have expected, if we increase the utilization rate of the staff, then the total number of man days to

clear the number of shortlisted applicants will be reduced. We can find the relationship between the number of shortlisted applicants and the number of man days required by using the **TRENDLINE** function in Excel. It is a linear relationship and the equation of the lines vary for different utilization rate is shown in Figure 6. This equation is used in the tool given to the manager to answer his manpower planning queries and what-ifs.

Figure 6: Sensitivity analysis by changing staff utilization rate



If we want to know, how many staff will be required to service all the number of shortlisted applicants within a month using the basic model 1, we can re-compute the number of staff required using formula below. Since the number of staff can only be integer value, we will round it up with zero decimal place using the **ROUNDUP** function in Excel.
Number of CSOs required = total time required (T_A1) / (22 * working hour * utilisation)

Figure 7: Number of staff required based on number of shortlisted applicants

Time period (Months)	Shortlisted Applicants	Number of staff required
1	2300	6
2	1897	5
3	3254	8
4	2056	5
5	1692	4
6	4586	11
7	1298	3
8	3490	8
9	2876	7
10	3987	10
11	3456	8
12	5348	13
13	3546	9
14	5498	13
15	3450	8
Average	3249	8

Figure 7 shows the number of staff required to service all the number of shortlisted applicants within a month. We ask students how they are going to help the organization to solve the manpower challenge. Some students suggested that they can hire part-time additional staff to fill up the resource requirement. Others mentioned that the company can pay the staff overtime to work extra hours. In any of those case, it is not going to solve the problem as there are limited talent and limited time that one can work within a stipulated time. However, there are also some operational constraints based on the real-business scenario, such as all the staff need to be full-time employees of the organization (i.e. security control) to service the customers. The new staff needs to undergo special on-the-job for at least 1 months and understudy with mentors before they can officially become CSOs to serve the customers effectively. The answer provided by the model cannot be used blindly as there are manpower budgets constraint. If we hire 13 staff to meet the peak at months 12th and 14th, there will be an additional overhead on the company operational expenses. Furthermore at other times, these staff will be idle and unproductive. From this point onwards, we discuss about how to utilize the human resources effectively and efficiently in an organization by finding out the optimal number of resource required with some recommendation for process changes. This leads us to the development of model 2.

Model 2: What-if Analysis

We have recommended that the company provide an online booking system so that the customers can choose the appointment after being shortlisted. In order to obtain the optimal number of staff required to service all the number of shortlisted applicants, we have suggested the company to have steady number of shortlisted applicants by opening a fixed number of booking each month via online portal. Customers are able to see the available number of booking next month after they are shortlisted and book online. If all the bookings are filled up, the company won't be opening up any new slots for the month, and the unfulfilled customers need to submit the application again. This will ensure that all customers are served within a month. If the human resource requirement is steady then they don't need to pay overtime charge which is 1.5 times the normal pay. It will be a win-win situation for the customers and the company.

Let us now use the same data and test our new approach. We need a model to find out the optimal number of staff required. Firstly, we get the average number of shortlisted applicants per month using the historical data, which is 3249, and we use the average number of shortlisted applicants per month and fixed utilization rate of 60% as an initial starting point. Then we use this simulated number of shortlisted applicants and compute the total time required and total staff required. To answer the question on “If we vary the number of shortlisted applicants by +/-20%, what is the impact on the manpower requirement?”

Sensitivity analysis is the one of most valuable concepts used in the dynamic business-environment studies. We limit this analysis to the impact of changes in the uncontrollable variable values to the business objective. In the case, given the unknown number of shortlisted

applicants or staff utilization rate, students need to explore how the optimal number of staff will be affected by varying different input values and illustrate the solutions in the table. We have added % of variation to get the new number of shortlisted applicants and the output that we need to compute is the total number of staff required. This computation is very similar to what we have found earlier. Using the total staff required, we can use the 2D **DATA-TABLE** function in Excel where the row input cell is the utilization rate and the column input cell is the number of shortlisted applicants' percent % variation. The output of the table is (Total staff required) in the table. The sample Figure **8** below shows the model 2 solution.

Figure 8: Excel solution for Model 2 – Optimal staff required

Model 2

Number of shortlisted applicants	3300	
% variation	0%	
New shortlisted applicants	3300	
Time required for A1	381.15	
Time required for A2	257.4	
Time required for A3	155.1	Demand
Total Time required	793.65	
total staff requierd	8	

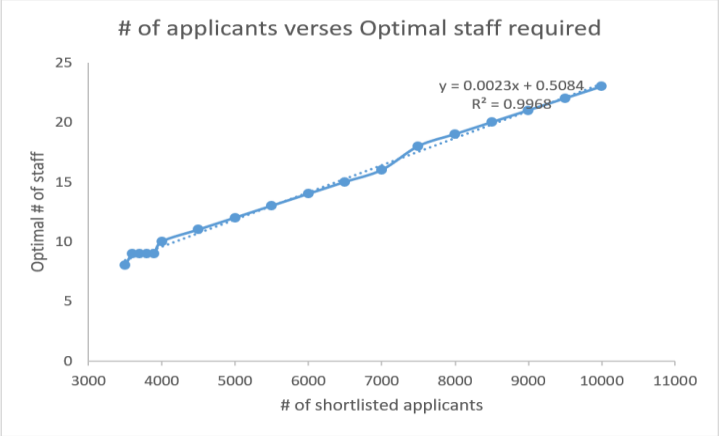
Sensitivity analysis by changing number of shortlisted applicants and utilization

	Utilization rate				
8	40%	50%	60%	70%	80%
-10%	11	9	7	6	6
-20%	10	8	7	6	5
-30%	8	7	6	5	4
-40%	7	6	5	4	4
-50%	6	5	4	4	3
0%	12	10	8	7	6
10%	13	10	9	8	7
20%	14	11	10	8	7
30%	15	12	10	9	8
40%	16	13	11	10	8
50%	17	14	12	10	9

Next, we can run the sensitivity analysis by varying the number of shortlisted applicants between 3500 and 10000 and find the optimal number of staff required. We can easily build the table using Excel **DATA-TABLE**. This table will give the company very useful information about the staff requirement verses the number of shortlisted applicants they can serve in a month. Based on the human resource budget, the manager can accept more number of shortlisted applicants while meeting the SLA. **TRENDLINE** is also added to the graph to give the relationship between the number of shortlisted applicants and optimal number of staff required per month. R2 value is 0.9968 which shows that this is a good fit to use for business. The result and graph for this analysis is shown in **Figure 9**. However, the model only serves as a decision support tool for the company's management, and it is up their discretion to make decision on the ground and manage trade-offs. Students are asked to explore what will be the next step for the company and the discussion ends here.

Figure 9: Number of shortlisted applicants verses optimal number of staff

# of shortlisted applicants	8.00
3500	8
3600	9
3700	9
3800	9
3900	9
4000	10
4500	11
5000	12
5500	13
6000	14
6500	15
7000	16
7500	18
8000	19
8500	20
9000	21
9500	22
10000	23



CHALLENGES IN CLASS

After teaching this course, here are some of the challenges we face in conducting the class.

- Student find it challenging to follow the concepts
- Student do not have past experiences of solving problem
- Student has no prior Spreadsheet Excel skill
- Student lack developed analytics skills

DISCUSSION AND CONCLUSION

Most students begin the case with little knowledge of the "world of business", except possibly through the eyes of current news in newspapers and television. The purpose of bringing students through such an exercise is to show them how to build exploratory model using spreadsheet as a simple tool. They also learn and practice features of spreadsheet that are relevant to the exercise. Most importantly, the case and all business case studies in general, help students acquire real-world experience in the classroom. It also shows how a spreadsheet model that can be built in about an hour and a half can be of practical use in the real world. It is good to start building the basic model in Excel from scratch and progress to advanced modeling techniques. For the first few lessons in the course, they find it hard to deal with the ambiguity, and to get started without much information being given. But after a few lessons, they learn to appreciate the power of the spreadsheet as a problem discovery and framing mechanism, and they can work towards creating models in which the inputs can be changed as easily and frequently as they want with the output still computed correctly.

We find it useful and beneficial if the students help each other during the class exercise as they can learn from each other. The instructor as a result becomes more available to other students who need deeper guidance. Towards the end of the session, the instructor can illustrate the workings and explain various correct and erroneous approaches to solve the problem and why one option is better than the others.

In summary, the case reinforces the following skills:

a. Analyze the historical data and get the generalized data summary for future use
b. Make assumption and build models for ill-defined real-world business problems
c. As opposed to making decisions based on "gut" feeling, models with valid assumptions are robust and start with simple model that can be enhanced for more complex business scenario
d. We must be able to suggest challenges to the business if it will improve the overall customer experiences and staff satisfaction

The results from the students' feedback shows that students find problem solving skills very important to real-world. This is also a transferrable skill to solve various problems. Excel is a good exploratory tool and it is useful to build the dynamic model using most parameters as an input and reference. Students are also reminded to make certain assumption to build the model and validate the results with users. They can also use Excel to run various scenarios and making decision based on scientific approach especially in today digital world.

On the whole, the problem-solving approach using Excel holds several advantages over existing lecture-based study. Compared to the lecture-based teaching, it has a very visual nature, is fun to play with, allows for collaborative learning, and provides immediate feedback to students about the key concepts that are to be taught. They can visualise the numbers using various graphs and charts, and they can modify the model accordingly if business environment changes. This case is intended for both undergraduate and graduate student levels; to determine the macro-level manpower planning for an organization. Spreadsheets are demonstrably useful, and students are encouraged to continue to hone their "business modeling with spreadsheet" skills.

LEARNING POINT FROM THE CONSULTANTCY PROJECT

Our journey continues. The whole workbook which includes model 1 and 2 has been given to the company. The manager uses it to solve manpower planning issue and improves the manager's productivity because the planning time has been greatly reduced from days to minutes. CSOs are happier as there is a more balanced workload distribution based on average service time by age group and service, rather than based on a fixed X minute per customer and total of Y appointments per day.

As an extension for this use case, we have also developed a predictive model to determine the appointment status (Show, No Show) with 85% accuracy rate. Subsequently, we use the predictive result and the output from macro-level planning (i.e. the number of staff required) and solve the staff scheduling problem. We are able to allocate each predicted "Show" appointments to staff subjected to working hour limit.

Manpower planning and staff scheduling are common issues in many other industries such as F&B, education, medical, service and others. We can use the same approach discussed here to

solve their respective manpower problem. Certain industries may operate round the clock, and some employees are bound by the union rule, which can then be calibrated into the model to adopt to various businesses' needs. From the above, we foresee that other manpower planning applications can be developed using our approach.

Teaching Warehousing with Excel

Vitaly Brazhkin
Western Illinois University
Email: V-Brazhkin@wiu.edu

ABSTRACT

This presentation highlights and illustrates several specific ways of using Excel to teach a warehouse management class in an online environment. Excel is well suited for warehouse layout drawings to scale and programmable exercises. Excel can be efficiently used in combination with the course delivery software to guide students through exercises and provide a tool to check intermediate and final answers. Finally, certain simple but often overlooked functions, like the rounding family of functions, can be taught as an auxiliary learning objective.

KEYWORDS: Excel, Warehousing, Teaching methods, Experiential learning

INTRODUCTION

Few colleges and universities offer formal classes in warehouse management as part of their supply chain curriculum, but those that do face a substantial challenge: there is no college level textbook of warehousing. Instead, the common practice is to use industry handbooks, such as those written by Richards (2017), Frazelle (2002), and Tompkins & Smith (1998). These books are addressed to practitioners and do not include problems or exercises, so instructors have to come up with their own.

This is where Excel comes in handy. Excel is a widely available application, and most students are familiar at least with its basic functions by the time they are ready to take the warehouse management class, so there is no extra expense or training involved.

Excel provides an excellent environment to create exercises in, including complex programmable ones, as well as drawings of warehouse layout for illustrations. It also works very well in tandem with any course delivery software. Additionally, a warehouse management class presents an opportunity for students to build skills using less common but useful functions in Excel.

All of these situations are described in more detail in this teaching brief. The examples are taken from a course taught online and are thus particularly beneficial for this format known to have limited options for student-instructor interaction.

THE ILLUSTRATIVE FUNCTION OF EXCEL

The ratio of length to height of a standard Excel cell is 3:1. This offers a great opportunity to draw a basic warehouse layout to scale by simply using the borders of the cells without any changes to cell sizes. In terms of scale, one cell can be assumed equal to 12 ft by 4 ft. A typical resulting image of a warehouse will have racks with 12-ft. bays and 12-ft. wide aisles commonly used for counterbalance forklift operation. The depth of the selective racks is 4 ft, but with two adjacent rows of racks, the depth could be assumed to be smaller, given the flue space. For a basic warehouse layout design problem, the flue space can be disregarded. Appendix 1 shows

a fragment of a warehouse layout from a problem which asks students to design an optimum layout of an addition to a warehouse, given the existing constraints.

The advantage of warehouse layout drawings in Excel is their simplicity paired with the true-to-life ratio of design element sizes. Creating this kind of drawing in another application, e.g., AutoCAD, would have been more cumbersome without any substantial advantage to the learning process. Students report that they typically find it very helpful when a warehouse layout drawing is supplied as an illustration of a complex problem or case. Besides, due to wide availability of Excel, students can actively participate in the exercise by drawing their own design in problems that call for creativity. Since no special skills beyond the basics are required, students can focus on the content of the exercise and not on how to make a drawing.

COMBINATION OF EXCEL WITH COURSE DELIVERY SOFTWARE

Using Excel in conjunction with course delivery software presents an opportunity to offer additional guidance and feedback to students on complex computational problems. The problem needs to be structured as an Excel spreadsheet. If the calculations require multiple steps, some cells may be designated as checks for intermediate results. The same color can be consistently used throughout the course for easy identification of these cells. Once a student has entered certain data and/or formulas in the input fields, the check cells will display the results. These intermediate results may be entered into the special tool, such as a quiz with a fill-in-the-blank answer format, in the course delivery software, e.g., Brightspace or Blackboard. The student than will see if the answer entered is correct or incorrect and will see any standard feedback that the instructor can program into the tool, e.g., a typical reason for getting an incorrect answer in that calculation. I set the help tool to unlimited attempts and do not make the scores on it count towards the grade for the exercise to encourage students to use the tool without any fear of spoiling their grades. For the help tool to maximize learning, the format should not suggest any specific answer, i.e. it should not be a multiple choice format. A fragment of an Excel exercise with cells marked “HELP TOOL” is shown in Appendix 2.

In the same way, final answer cells can be designated by a certain color, and a quiz can be set up where students will enter their answers. For difficult problems, I recommend two attempts for the final answers quiz. After the first attempt, the students will be able to see their score for each question and read the feedback. If any questions have been answered incorrectly, they have a second chance based on the feedback. Even if the multiple computational steps are consecutive and only one final answer is expected, it is possible to use answers to some of the intermediate steps in the quiz, so that a partial credit can be given to students who completed several steps but have not arrived at the correct final answer, in the same way a partial credit would be given if the whole spreadsheet was submitted for grading.

This system may look complex to program, since it takes two quizzes for one problem with multiple answers. However, once the setup is finished, the instructor’s time is saved, because everything is graded automatically by the course delivery software. This advantage becomes substantial for larger size classes. Besides, compared to the alternative of the students simply submitting their Excel sheets for grading, the use of Excel paired with the course delivery software provides a high level of interaction. This guidance is really appreciated by students. Its additional advantage is its immediate availability to students on their terms compared to a student e-mailing a question or request for help to the instructor and then waiting for a response for an uncertain period of time. The availability of the help tool with unlimited attempts encourages students to experiment and promotes experiential learning. Clearly, this type of

Excel use in tandem with the course delivery software is not specific to warehouse management problems and can be recommended for other classes with computational home assignments.

COMPLEX EXERCISES AND CASES IN EXCEL

In addition to problems requiring straightforward calculations, it is possible to use Excel to develop case-like complex problems that will teach students analytical skills. As an example, my students of the warehouse management class are assigned an optional homework requiring to solve a problem of a potential shortage of space in a warehouse due to a planned change in operations. The warehouses block-stacks pallets three tiers high, and the potential solution is to add a fourth tier. However, there are several constraints that students have to evaluate and overcome (pallet weight limit, building clear height, forklift lift capacity, and others). The constraints are defined by formulas and explained in words. All the constraints translate into five tests that must be satisfied to add a fourth layer. However, when a student changes the number of tiers from three to four, several of the tests turn from the green “pass” to the red “fail.” From that point on, the student starts to investigate which constraints the failed tests will lead to and how to overcome them, e.g. replace the currently used pallets with higher capacity pallets.

The way this exercise appears in Excel is shown in Appendix 3. Unlike using Excel tables to provide data for a case written as text, the whole case is contained in one Excel sheet, and students are expected to solve the case by primarily experimenting with numbers in the sheet and receiving immediate feedback from the five tests contained in the sheet.

Setting up an exercise in a form of a structured case in an Excel spreadsheet promotes experiential learning. It is an exciting exercise for students who love solving puzzles and many students report that they enjoyed working on this exercise. However, due to its difficulty, it is offered as an optional exercise with bonus points only. The example discussed above, while specific to warehousing, illustrates that Excel can successfully be used for complex, case-like problems to develop analytical skills, which is highly appreciated by advanced students in any class.

BUILDING EXCEL SKILLS PER SE

So far we have focused on ideas that do not require additional skills in Excel beyond the basics students are already expected to have. However, there are certain useful functions in Excel that are relatively simple but are commonly overlooked. So why not teach a few of them in a warehousing class?

For example, there is a whole family of rounding functions that allow rounding up, down, to a certain number of digits before or after the decimal point and rounding in special increments. I have built all of them into a warehouse design exercise in a way that teaches the appropriateness of using a particular way of rounding, e.g., length of a rail dock in 75-ft. increments, the length of a typical railcar served by the warehouse.

The learning objective of discovering and using new Excel functions is secondary in this exercise, but because it is well integrated into the fabric of the exercise, the learning becomes very memorable. The key for the instructor is to identify a good opportunity for blending new Excel functions into an exercise. Learning about which Excel functions students are likely to know or unlikely to know from other classes should also help to understand whether the functions used will be complementary to the already existing Excel skills of students or will come as a reinforcement of those they have already learned. This will determine the strategy of

introducing the functions into exercises or problems. For example, the rounding functions of Excel are new to most students, so to help them, I provide a one-page rationale for using each of the rounding functions.

CONCLUSION

Without a warehousing textbook, instructors are left to design their own problems and exercises to teach quantitative aspects of warehouse management. Excel is an ideal tool to use in a warehouse management class to reach four specific objectives:
(1) teach warehouse layouts by providing illustrations and environment for students to easily to modify them or create their own;
(2) develop analytical skills through complex problems and cases set up as Excel spreadsheets with feedback options;
(3) provide convenient feedback and guidance to students by combining Excel based exercises with help tools and quizzes built in the course delivery software; and
(4) integrate some of the new or less known Excel functions into Excel based exercises to provide students with an additional benefit of expanding their Excel skills.

This teaching brief used examples from an online warehouse management class to illustrate the teaching techniques, but these objectives are not limited to a warehouse management class; the approaches and techniques described here can successfully be used in other classes as well.

	Lift Capacity, tiers	1										
	Safe Lift Capacity, tiers	1										
	Most Restrictive Lift Capacity, tiers	1										

Green and red cells contain formulas!
They are explained below

A tier is defined as a pallet with a load.

ENTER DESIRED TIERS: 3

	Checks:	**Weight**		
	Desired # of tiers vs. the most restrictive stacking limit in E25	Most Restrictive Limit	PASS	**Test #** **1**
	tiers*Loadweight + (tiers - 1)*Palletweight	Pallet Capacity	PASS	**2**
	Checks:	**Height**		
	tiers*(PalletHeight + LoadHeight) + PalletLift	Bldg Clear Height	PASS	**3**
	Sum of heights of tiers on the floor before the top one(s) is added	Lift truck actual extended	PASS	**4**
	Sum of heights of tiers on the floor before the top one(s) is added	Top Pallet(s) Lift (Lift Truck	PASS	**5**

YOUR TASK: Your warehouse receives a lot of this product for storage. The relevant details of the product and pallet it comes on are in columns B through E and the forklift capacity table is in the top box above. You block-stack the product three tiers high. However, a 20 to 25% increase in the amount of this product is required soon without any changes to your storage capacity. So you are thinking if perhaps you could store the product four tiers high that will solve the problem. There are many factors that you need to consider, so you have prepared a helpful table that lists all these factors and provides five weight and height tests for a four-tier storage. All you have to do is enter the number of tiers you want to use in the blue cell in the box above and the table will show if it passes all the five tests. All five tests must be met for you to implement your solution. Unfortunately, some turn from "PASS" to "FAIL" as you replace 3 with 4 in the blue cell. However, your next best solution of storing the extra product in a public warehouse is expensive and inconvenient. So you'd rather spend a little time to figure out what you can change in your operation to accommodate the 4th tier. You are prepared to spend a reasonable amount of effort, time and money, but you cannot change the clear height of the building, any safety standards or the calculation formulas. So is there a solution? Please recommend the best solution in the box below and highlight with color the cells where you have modified the values. Your decision box above should show 4 tiers and all 5 tests should be a "PASS". Submit the modified file with your answers through Assignments by the deadline.
Highlight all the changes you have made in the table with a distinct color.

The purpose of this task is to reinforce the knowledge of the factors that influence stacking decisions and to develop problem-solving skills in a complex multi-factor, multi-relationship situation. Most of the data are realistic, even though some had to be modified to make this an educational activity.

ABSTRACT

The aim of this study is to analyze reviews of “Internet of Things (IoT)” related products by using text mining. Apart from sentiment analysis, our anticipated goal is to find out the features of IoT products appeal the most to the consumers. Based on the clustering results, we were able to draw conclusion on common advantages of IoT products and provide suggestions to the technical improvement as well as some useful business strategies from aspects such as private issues that most consumers shared with their concerns.

KEYWORDS: Internet of things, Text mining, User experience

INTRODUCTION

The internet of things, IoT, refers interrelated computing devices capable of transferring data over a network without human-to-human or human-to-computer interaction, which are often equipped with ubiquitous intelligence. IoT is also defined as connecting things by internet based on information sensor equipment to achieve information exchange and remote management. With the rapidly development of Internet of Things technology, the concept of smart home became very popular, but if someone can use the network to break into the security line of smart home products, such as: thermostats, smart TV, camera, etc., they can easily obtain privacy information. In other words, IoT products impose potential security risks. (Bandyopadhyay & Sen 2011) (Suo et al. 2012).

The aim of our study is to select reviews of popular IoT products from Amazon,, perform clustering analysis by using SAS Enterprise miner to find out what features of IoT products

attract consumers, as well as attributes that cause negative opinions. In conclusion, suggestions and prediction of the trend of the development of IoT are provided

LITERATURE REVIEW

The concept of a network of smart devices was discussed as early as 1982, with a modified Coke machine at Carnegie Mellon University becoming the first Internet-connected appliance. (Bandyopadhyay & Sen 2011) (Bonomi et al. 2014) As of 2016, the vision of the Internet of things has evolved due to a convergence of multiple technologies, including ubiquitous wireless communication, real-time analytics, machine learning, commodity sensors, and embedded systems. (Ng & Wakenshaw 2017) However, for the development of IoT, security is a major concern for this young industry. Lack of IoT security expert makes it very difficult to avoid the risks of attack from hackers.

According to conservative estimates, the number of global embedded chips, sensors, radio frequency smart objects have exceeded 1 trillion (Bin et al. 2010). Security and privacy are the key issues for IoT applications. The IoT industry is facing enormous challenges, for example, the privacy problems confused people, the limitation on the platforms, the number of equipment make it hard for upgrade and maintenance, operation based on cloud is neither effective nor reliable. **(**Suo et al. 2012) Even with such huge challenges, IoT products are still appealing to many more consumers because of their convenience to people's daily life.

Prior research (Ng & Wakenshaw 2017) has suggested that consumer experiences with physical products are highly visible in the era of IoT. In this study, we perform analysis on customer reviews of IoT products to gain valuable insight on these products.

DATA COLLECTION

In data preparation phase, we started searching original data from IoT related literatures, IoT products' reviews from Amazon.com, and IoT related social media platform posts. We used data mining software "Octoparse" and a Google Chrome extension tool "Data Miner" to identify potential data for analysis. For the purpose of this study, we decided to use "Data Miner" tool to extract top ten IoT products' reviews from Amazon.com.

We selected ten target products from http://iotlist.co/. Each product has over 1,000 customer reviews. The 10 products we selected were: Apple Watch, Echo Show, CUJO, Echo Dot2, Fat Scale, Fithitsurge, Google Wifi, Nest Cam, Smart Light and Smart Plug. We chose an existed public script to start raw data collection in "Data Miner". After running the data mining code, we downloaded six columns of data of the selected IoT products from their customer reviews: review-title, review-text, verified purchase or not, number of helpful, number of stars, date of review.

Data pre-processing on all the ten product review files was performed after raw data were collected. The reviews that were not verified purchase were filtered and deleted. This is to make sure all reviews we would use for text mining are reliable. The data files are then prepared to use in text mining and clustering analysis.

CLUSTERING ANALYSIS

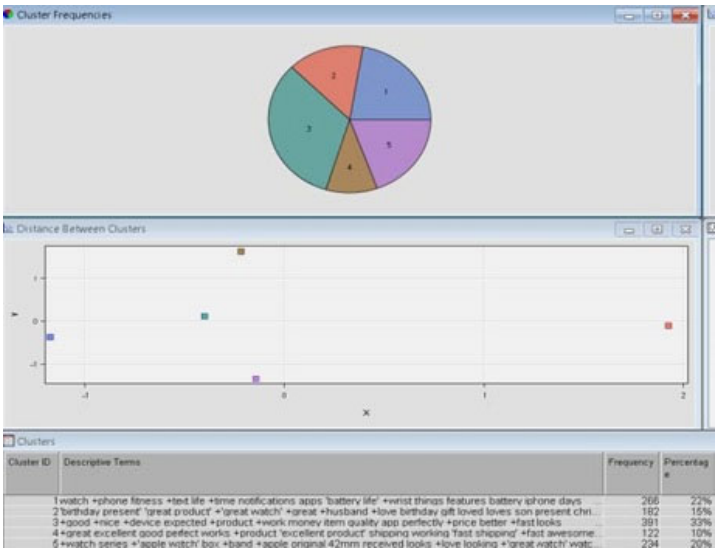
Clustering analysis was conducted using SAS Enterprise Miner. The purpose of clustering analysis is to discover common features, as well as current issues of IoT products from consumers' perspectives. After data preprocessing, the first step is to choose adequate configuration parameters in SAS. Several trials were conducted by adjusting parameters used in SAS Text Mining. Parameters such as term weights, frequency weights, SVD dimensions and resolutions were considered. We found that when the Max SVD Dimension is set as a larger number, or the SVD resolution is set as high, the results tend to be of less clusters. In these cases, some important information may be hidden. When both parameters were set lower, the results will be of more clusters. However, more clusters may not necessarily mean better outcomes. The examination of consumer reviews in each cluster was done manually. We needed to make some decision on the selection between cluster numbers and the accuracy of clusters. Finally, we chose to compromise between more clusters and a higher accuracy, and chose "medium" as SVD resolution, and "medium" as Max SVD Dimension.

In order to better determine the characteristics of each cluster, we set the number of descriptive term as 15; the clustering algorithm as Expectation-Maximization and cluster number as "maximum equals 20". We ran SAS for the first time and analyzed the results. Based on the result, we altered the settings for each product, then repeating this process to obtain ideal results.

The analysis on IoT product Apple Watch

The first product we analyzed was Apple Watch. Figure 1 shows the result of the clustering analysis of the reviews of the Apple Watch sold on Amazon.

Figure 1: Clustering analysis of the reviews of Apple watch



The result has five clusters in total. We summarized the features of each cluster by the descriptive terms for the cluster. We found the first cluster is about the quality and lifetime of this product, according to the key words such as "battery life".

The second cluster is related to considering the product as a gift. By checking the review text, we found many people think Apple Watch is a wonderful choice to give to their friends or relatives as presents.

The third cluster basically focuses on price. We found some people mentioned about the price of Apple Watch, such as “good price”, “worth it”.

We also discovered outliers exist in each cluster. People may not necessarily be talking about exactly the same things as the cluster summarized. Especially in cluster 3, there are some comments like “great”, “excellent”, which may represent some kind of positive sentiment toward the product, but not specifically illustrate any features, such as price.

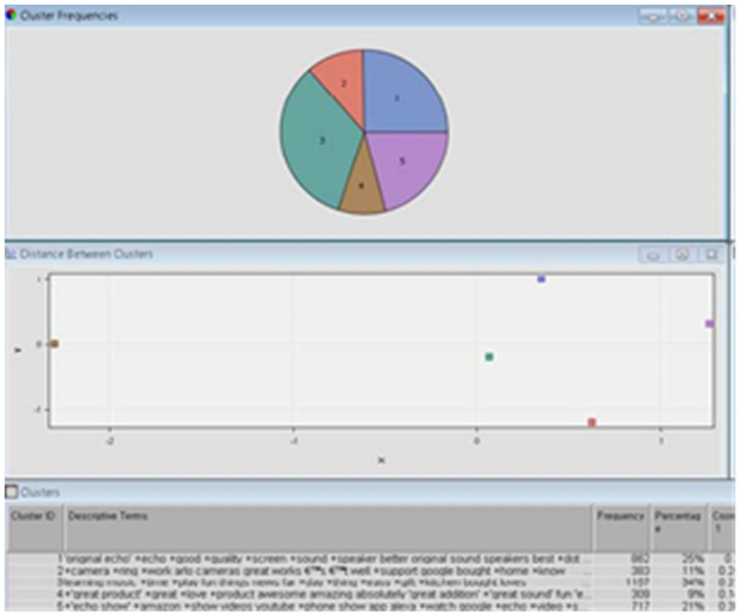
The fourth cluster including information of shipping. People had comments like “fast shipping”, “fast delivery”, etc.

The last cluster talks about the beauty of the products. The exquisite looking is also an attraction to many people.

The analysis on IoT product Echo Show

Second IoT product reviews we analyzed were the comments of Echo Show on Amazon. Clustering analysis similar to Apple Watch is performed and the results are shown in figure 2.

Figure 2: Clustering analysis of the reviews of Echo Dot2



As can be seen from the description of the clusters, Echo Show has great sound, which is a major attraction to people. The second cluster indicates that a good camera is also a huge benefit. Music is the keyword of the third cluster. Obviously, Echo Show plays good music which

people love. From the fourth cluster we know that this product really give lots of fun to customers. The last cluster tells that people care about those videos on flat platforms like Youtube, which provide support for Echo Show that makes it a more competitive product.

The summary of analyses on other IoT products

As mentioned previously, we have conducted clustering analysis for the top 10 products on Amazon, apart from Apple Watch and Echo Show. We also analyzed CUJO, Echo Dot2, Fat Scale, Fithitsurge, Google Wifi, Nest Cam, Smart Light and Smart Plug. Similar text mining analyses are conducted for the reviews of rest of the IoT products. The summaries of clustering results are descried as follows.

For CUJO, there are four clusters about good customer service, good functionalities, convenience to setup and use, as well as the ability of parental control.

As for Echo Dot 2, the key words are price, functionalities, good looking, good quality and enjoyable light or light.

For Fat Scale, people care about price, convenience, sturdy batteries, good for fitness and financial issue.

For Fithisurge, there are a lot more clusters than other products we analyzed. We found clusters for battery, weight tracking, heart rate monitor, warranty policy, nice to wear, good screen and husband love respectively.

The next one is Google Wifi, the important things about the product are signal, connection problem and convenience of setup.

As for Nest cam, stand out points are convenience of installing, good cable, good camera.

The last two products are Smart Light and Smart Plug. For the former one, people focus on connection issue, nice color, convenience of control and good price or quality. For the later one, people focus mainly on link issue, remote control, smart control, lovely turn on as well as convenience of setup.

According to the summary of these products, we are able to find some common features that they share, especially, convenience, fitness as gifts, good functionalities. Besides, we also noticed a small portion of the results is about people's concern, such as privacy issue and security.

CONCLUSIONS AND FUTURE RESEARCH DIRECTIONS

Based on clustering analysis, we found common features of IOT products, which people interested in, and features that people concern about. Based on the summary, suggestions can be made for example the company may improve the packaging of IOT products since many have commented on such issue. Others improvements may include: Fixing/reducing technical problems such as poor signals; improving security and privacy issues.

These suggestions are those points summarized from our study that we think IOT products can improve as well as some business tactics which can be useful in improving sales. We think with

the right business strategies and technical improvement, in the future, IOT products will reach a greater success in the market.

There will be more and more intelligent hardware in the future, to connect to the Internet all the time. IoT services and products are promising in the near future across various industries. In the next step, we plan to add and analyze more product reviews to draw comprehensive and interesting conclusions. Also we plan to look into the analysis segments based on various timelines to perform trend analysis as well as to refine the setting of clustering analysis in SAS.

We plan to identify weakness of IoT products. From an academic point of view, adding more literature review as out data resource is also one of our future works. The last thing is to extend our research area to other field like public transportation, supermarket or hospital.

ABSTRACT

This study aimed to understand how to set up the daily process of decision making related to productive capacity. The research was carried out through six semi-structured interviews. The findings showed that productive capacity decisions are divided into routine and strategic decisions and is guided by rational and intuitive processes.

KEYWORDS: Management decision-making process, Productive capacity, Port environment, Reason, Intuition

INTRODUCTION

The port context has been evidenced as an important link in the intermodal transport chain. Therefore, the need for optimization of port management in order to reduce cost of cargo handling has been increased (Mabrouki, Bentaleb & Mousrij, 2014). To analyze this context, it is necessary to consider that port activities are impacted by many factors, including the dynamics of the world economy, the limitations of port space, cargo handling restrictions, high storage costs, strikes, oversight, inadequate training of personnel, and constant relations and negotiations with public agencies (Lee & Park, 2016; Serra, Martins & Bronzo, 2009; Zampirolli, 2017).

Given this reality, the operation manager in the port context ends up having a fundamental role, since its decisions can impact the productive organizational capacity. However, the current literature on decision making in the port context has been based fundamentally on a more traditional chain. The focus is, for example, on measurement models that seek to identify port strengths and weaknesses in order to provide information that provides optimal strategies to

improve performance (Ha, Yang & Heo, 2017), in specific methodologies for identifying and evaluating (Mabrouki, Bentaleb & Mousrij, 2014) or in the hierarchy of port operations interactions.

In this context, it is possible to realize that what is expected are managers who make decisions based on paradigms grounded on traditional rationality and analytical models of information processing, given a large amount of data and information present in organizations, as well as the advanced technologies that support managerial activities (Agrawal, 2014). Thus, it is believed that the use of formal logic results in the best solution available to any problem faced in any circumstance (Simon, 1947).

However, it must be considered that tool-technology, as well as all information concerning a scenario or a problem situation, will not always be available to the decision maker (Hymowitz, 2001), much less in a complex and specialist context such as the port (Lee & Park, 2016; Serra, Martins & Bronzo, 2009; Zampirolli, 2017). Additionally, the decision can be developed in contexts of multiple actors, organizational and environmental constraints and its potential consequences can be difficult to be evaluated in their totality (Huy, 1999; Weick, 1990).

Thus, it is important to look at other elements that guide the decision-making process, that is, to a more subjective and intuitive nature. The relevance is to understand how they influence, complement and participate in managerial decision making. This can bring relevant contributions to the advancement of emerging approaches in Decision Making, in which such decision drivers find refuge and space (Agor, 1986; Dane & Pratt, 2007; Sayegh, Anthony & Perrewe, 2004).

In this way, the article seeks to fill this gap by explaining how rational and intuitive decision-making are configured in decision-making contexts of productive capacity. Therefore, we try to answer the following research problem: How it is set up the day-to-day decision making process related to productive capacity, given the huge amount of data and information available in organizations?

This study is justified from the following points. First, the reflections here woven walk against the traditional theories speech of Decision Making in management, which consider that the decision based on rational/analytical thinking is what gives greater assertiveness of results at the expense of intuitive decisions (Simon, 1947). Also, we seek to articulate intuition and emotion as critical and influential elements of the decision-making process from emerging approaches to decision making (Carter et al., 2017; Huy 1999; Sayegh, Anthony & Perrewe, 2004).

Second, much of the focus on the development of decision theory so far is related to rational and behavioral aspects of decision making under normal conditions, that is, without the occurrence of atypical events. In this way, it is important to go a step forward on managerial literature, giving attention to the development of theory under decision-making contexts related to risk, uncertainty and time pressure - considered atypical (Sayegh, Anthony & Perrewe, 2004).

Finally, from a practical point of view, this study becomes fundamental in launching a differentiated look at the decision-making process in the port context, usually analyzed in the light of more traditional perspectives, as in the studies of Ha, Yang and Heo (2017), Lee and Choo (2015) and Mabrouki, Bentaleb and Mousrij (2014). The purpose of this work is to contribute to the field by bringing to the fore the use of intuitive aspects as fundamental elements for the decision-making process of port operational managers.

In this sense, the central argument of this study is based on the understanding that there is no "pure" and "ideal" type of decision-making. In fact, what exists are variations of this relationship, that is, rational and intuitive, one being used more clearly, and another depending on the type of configuration of the decision and the type of context in which it is being articulated. Thus, it is assumed that this relationship is inseparable and can make the decision-making process and its results richer and more contributory.

LITERATURE REVIEW

Rational Decision Making

The rational decision-making process is characterized as deliberative, structured and quantitative. Based essentially on logical mental processes, in which decision-making follows an orderly logical sequence, supported by a wide range of statistical tools (operational research and management science) and expert systems technology. The term rational - or logical - is applied to decision making that is consciously analytical. It analyzes problems systematically through the modern arsenal of analytical tools provided by managerial science and operational research (Simon, 1956; 1979; 1987).

Thus, taking as an example the port activity segment, characterized by the high technicity, specialization of the workforce and standardization of activities (Serra, Martins & Bronzo, 2009; Zampirolli, 2017), it is assumed that in this environment configuration of rational decision-making are frequent. Consequently, this context turns an interesting locus of study to understand how managers deal with the amount of data and high technology tools they have at their disposal, as well as with the analytical capabilities of their teams in the configuration of their decision processes (Sincorá, 2016).

Thus, to support the predominantly rational management decision-making process, it is observed in the literature that several researchers have focused on the development of analytical tools for solving problems related to the management of port terminals. Robenek et al (2014) developed an algorithm to optimize the allocation of ships on the berths and the organization of stock in the yards. To address the problems of daily shipyard allocation and crane utilization, Zhen et al (2017) proposed a programming model considering the tidal restrictions and the flow control in the channel. Due to the dynamic nature of the decision problems in a container terminal, Rida (2014) designed an optimal sequence of decisions, based on the Markov Decision Process (MDP) - mathematical model that considers that only part of the situation is under the control of the decision maker - to minimize the total dwell time of ships on the berths.

Zhu et al (2018) developed a computational simulation model to determine the capacity of a coal export terminal regarding to the terminal layout, equipment efficiency, unloading and loading processes, and frequency of ships and trains arriving at the terminal. Legato, Mazza, and Gulli (2014) constructed a simulation and optimization model integrating the tactical and operational levels to support decision-making regarding problems in the allocation of cots. In the same way, Zhen (2015) studied the problems of allocating berths to container ships that periodically dock at a terminal, given the uncertainties that hinders the decision-making process. Also, Pratap et al (2018) analyzed the operation process of a solid bulk terminal and proposed a model of decision support for managers based on rules that aim to minimize the time spent by ships in port.

Intuitive Decision Making

Simultaneously to the rational decision making, it is possible to consider the decision making as intuitive (Simon, 1987). Due to the increasing uncertainty and complexity that managers face in their work environments, it becomes almost impossible to rely solely on a rational decision-making process (Carter et al, 2017), thus opening space for the practice of intuitive decisions.

Also, intuitive processing was reported as effective under conditions of time pressure and uncertainty (Carter et al, 2007; Dane & Pratt, 2007).
Using a unifying concept of intuitive decision-making (Carter et al, 2017), the configuration of this type of decision is processed in two ways: experience and emotion. When based on experience, decision-makers commonly recognize parallels between decisions made in the past with the current one, and so decide accordingly with it. This approach happens because past situations provide suggestions that give "specialized access to information stored in memory", called tacit knowledge (Carter, Kaufmann & Wagner, 2017; Simon 1987).
Emotional processing, based on emotional and affective aspects, happens more often in situations considered uncertain, in which managers experience "intestinal feelings" or "growing excitement in the stomach" so that the propagation of such sensations affect the configuration of decision-making processes. Thus, it is assumed that intuition includes affections or feelings that guide decision-making and action (Agor, 1986; Carter, Kaufmann & Wagner, 2017).

Rational-Intuitive Decisional Processing

The disciplines of psychology and management suggest that intuition can complement rationality as an effective approach to decision making (Carter et al, 2007; Dane & Partt, 2007). Researchers who advocate a dual-process approach – that is, which differentiates a rational system from an intuitive system – assume that these two knowledge systems work together in decision-making. Also, scholars of this thematic present a variety of recommendations on how to use intuitions in combination with more rational decision-making. Simon (1987), for example, asserts that effective managers do not have the luxury of choosing between analysis and intuition – experience involves the use of both types of decision-making. Hodgkinson and Sadler-Smith (2003) argue that the ability to switch between “mental habits” and “active thinking” is the ultimate skill of today's organizations.
Shapiro and Spence (1997), using the same ideas, explain that the ordering of the two types of decision making is also important. They suggest that intuition should be recorded first, followed by a more thorough analytical assessment of the problem. The degree to which rational decision-making must be emphasized, however, must depend on the nature of the task (e.g., structured or unstructured). In contrast, Agor (1986) points out that many managers use intuition after engaging in rational analyzes, to synthesize and integrate the information collected and analyzed.
In 2010, Lejarraga and Gonzalez conducted an experimental research in order to understand how individuals based their decisions on binary choice problems with and without risk prospects. In this way, decisions based on descriptions (rational) and experience-based (intuitive) were analyzed. The results pointed out that depending on how the decision-making scenario presented itself to decision-makers, they had shown themselves to be heavily dependent on experience even when accurate descriptive information was available to them. This trend was marked in decision scenarios with complex descriptions, but, curiously enough, the same pattern was observed for decision scenarios with simple descriptions. This finding revealed that even in the presence of descriptive information about the choice options, individuals still tend to also consider their experience to decide.

METHODOLOGICAL PROCEDURES

Data Collection

This study had as a premise the qualitative research, which aims to interpret how a particular social phenomenon is daily constructed from routines, dilemmas, and problems that permeate the experiences of individuals (Bansal & Corley, 2011). The use of this research perspective is in line with the proposal of this study since it aims to understand how the process of decision-making linked to productive capacity is configured from intuitive, emotional and analytical questions.

More specifically, this study was developed in the port context, considered as an important link in the intermodal transport chain. Within the ports, loading time and production management are relevant aspects, as they influence the economic viability of the terminals (Mabrouki, Bentaleb & Mousrij, 2014). These elements, in turn, are impacted by a series of events that make it complex, such as the dynamics of the world economy, the limitations of port space, cargo handling restrictions, high storage costs, strikes, inadequate training of personnel and constant relations and negotiations with public agencies (Serra, Martins & Bronzo, 2009; Zampirolli, 2017). Given these elements, the manager in the port context ends up having a fundamental role, given that their decisions can impact organizational productive capacity.

Therefore, studying the decision-making of operational managers in the port context becomes crucial, especially based on the idea that decision-making can be characterized in different ways (Simon, 1987), depending on uncertainties and daily events experienced by managers. This discussion represents what Colquitt and George (2011) point out as a starting point in the selection of a topic of study, given that it contributes to the advancement of a great challenge in the port environment, which is the investigation of the dynamics of decisions in this context.

The technique used to collect the data was the interview, which comprises a discursive event in which social occasions can be identified (Spradley, 1979). More specifically, a semi-structured interview script was developed, which allows researchers flexibility in the order and group of questions, even in the face of a previously defined interview schedule.

It was decided to follow the ideas of Spradley (1979) to enable the interview in the elaboration and conduction of the technique. Thus, the initial questions were characterized by the more descriptive aspect, with broader questions aimed at highlighting the daily activities of the interviewees, as well as the history until they became operational managers in the ports where they work. Then, the structural questions were asked to reveal how the interviewees organize their knowledge about the context they are experiencing. The focus was on questions that sought to explore, for example, how respondents make decisions, what types of decision support they receive, and what difficulties and facilities they face in decision-making. Lastly, contrast questions were asked to highlight possible differences or contradictions in the interviewees' speeches. Thus, it was sought to point out to questions about satisfactory and unsatisfactory decisions of managers' daily decision-making process, and to ask when managers felt it was better to make decisions based on reason, intuition or emotion.

The interviews were conducted with six operational managers in October 2017. All of them work in different ports in the Southeast and Northeast of Brazil. For this reason, the interviews were conducted via Internet, through Skype software. Regarding the recording, the voice recorder Almolto Call Recorder was used, which is an extension of Skype that allows to record voice calls. After being recorded, all interviews were transcribed in the Word text editor.

The choice of interviewees was based on the following criteria: 1) to opt for managers operating in the national port segment, considering the particular difficulties faced in the economic viability of activities in the Brazilian port terminals (Lee & Park, 2016; Serra, Martins & Bronzo, 2009; Zampirolli, 2017); 2) opt for managers of operational level, considering that the forms of strategic decision making of these subjects is aligned with the purpose of investigating the decision-making process related to productive capacity. This aspect is considered important for

this article because it seeks to discuss how the decision-making process can provide significant value when integrated at the operational level (Bon & Broersen, 2017).
The choice of research subjects was made possible through a key informant, which is part of the personal network of contacts of the authors of this article. The informant had already worked with the operational managers interviewed, which was crucial to gain access to the field and to develop the interviews. Given this, there was a significant concern on the part of the interviewees to respond in detail to each of the questions.

Data Analysis

Some criteria become important when analyzing data in qualitative research, such as the attribution of meaning, compatibility between theory and what has been observed, generalization capacity, consistency, reproducibility, precision, and verification (Corbin & Strauss, 1990). In seeking to understand how decision-making related to productive capacity is configured in the port context, this study seeks to reveal the criteria mentioned above. For this, content analysis was used as a method of analysis, to make inferences about who, whom, how, with what effect and why an individual says something in a given context (Franco, 2005).
The recording unit adopted in the analysis was a theme type, in which the researcher seeks meanings and meanings in the statements highlighted by the data sources (Franco, 2005). To define the themes, we chose to follow a coding process suggested by Corbin and Strauss (1990), which followed the stages called Open, Axial, and Selective coding. In a complementary way, we considered the authors Glaser and Strauss (2006) and Ryan and Bernard (2003).
Data from the interviews were read from a repetition process (Ryan & Bernard, 2003). Following the orientations of Ryan and Bernard (2003), this initial reading of the data had the objective to find the events, expressions, and ideas that arose with more recurrence. For each moment in which these events were perceived, keywords or phrases were noted.
These annotations were fundamental to begin the process of open codification, which made it possible to start identifying the most recurrent themes in the interviews. Performing the coding process is a fundamental step for data analysis since it transports the researchers and their data to the theory used (Corbin & Strauss, 1990). Thus, some codes have been aligned with the base literature used for the construction of the work (e.g., “tacit knowledge” and "analytical thinking") and others have emerged *a posteriori* (e.g. “decision cost”). In all, 171 codes were found.
Also through the open coding process (Corbin & Strauss, 1990), the codes were compared among themselves to find similarities and differences between them. After this process, codes with similar incidents were grouped into ten blocks (intuition, rationality, decision-making contexts, decision-making cost, analytical skills, professional experience, port operations, decision support, intervening elements and decision-making style) categories and subcategories.
Next, analysis notes (memos) were generated by selecting groupings of codes that had some link between them. With this, the emergence of two main categories could be identified: routine decisions and strategic decisions. Also, we observed the manifestation of two subcategories inherent to the two main categories: decision-making and decision-making. This procedure called memos proves to be significant in the qualitative research scenario because it supports the formulation and revision of theories (Corbin & Strauss, 1990).
Therefore, the next step was to perform the axial coding (Corbin & Strauss, 1990) in an attempt to establish a relationship between the subcategories and their respective categories, and between the categories themselves. The two types of the decision were articulated by two subcategories, classified in the following terms: a) type of context (normal operating situations, under risk/uncertainty and under time pressure); and b) type of decision-making (based on

intuition, reason or both simultaneously). This stage of analysis was fundamental to investigate similarities and differences between subcategories to avoid overlapping as well as to understand what would be verisimilar among the main categories.
The above ideas allowed to proceed to the selective coding stage, which included highlighting the central category, a consequence of the point of interaction between the two thematic categories that emerged from the data. For this, the comparative method proposed by Glaser and Strauss (2006) was adopted. From this method, it is found that, regardless of the type of decision that the operations manager takes, that is, whether routine or strategic, he is always balancing the analytical and intuitive thinking during the configuration of his decision-making process. That is, these thoughts can be understood as decision drivers.
Such a finding has led to the central category, so-called "intuitive-analytical processing," which reveal that there is no "pure" and "ideal" type of decision-making. In fact, what exists are variations of that relationship, one being used more clearly, the other depending on what is being decided. Thus, it supposes that this relationship is inseparable and can make the decision-making process and its results richer and more contributory.

PRESENTATION OF RESULTS

Based on the interviewees' statements, it became possible to characterize part of the port context, as well as to understand how operational managers configure their decisions regarding to productive capacity, which is important for the continuity of operations, adequate customer service and performance satisfactory.
The ports researched are constituted by an infrastructure that includes several services, in which different types of operations are carried out. Among them are the transport and movement of important goods to society. In these operations, the manager must meet certain prerequisites such as compliance with labor safety standards and adherence to environmental laws. In addition, since there is a lot of variability in the port market, not being a fully automated and technology-controlled market, there is still a lot of room for improvement. This situation requires the manager to constantly seek the insertion of new methodologies, especially those that allow the migration from a prevention scenario to a risk management in different types of operation.
In relation to the managers interviewed, they are all from the area of operations, with academic degrees in engineering, computer science, and administration, as well as postgraduate in areas that have given them expertise to the function they hold today. Among their various responsibilities were to supervise teams and projects in development, to check operational results, to coordinate maintenance activities of equipment, to interface with external entities (e.g., navy, maritime pilotage environmental and regulatory agencies, unions, etc), to provide a safe and pleasant environment for the workforce, to meet customer needs, to loading and unloading cargo, schedule ship arrivals and departures, allocate and organize merchandise in the warehouse, and manage the flow of the yard and transport of cargo. Therefore, it can be seen that the body of activities administered by managers is one that directly interferes with the productive capacity of the port.

Port Productive Capacity

The productive capacity of the port is related to the maximum level of value-added activity that a port can carry out in a certain period, under normal operating conditions. Since they do not manufacture products but storage capacity, the operational managers interviewed need to plan

and administer activities that have a direct impact on this capacity, due to the obligation to meet the current and future demand of customers.
In this sense, in managing the productive capacity, managers articulate different types of decisions to allow the continuity and full operation of port operations, especially, assertively using facilities, equipment and labor highly technical and specialized. Such decisions generally refer to activities related to mooring and departure of ships, loading and unloading of goods, maintenance of equipment, yard and warehouse organization, as well as activities inherent in the purchase and rental of machinery, outsourcing of services, permanence and closure of contracts, promotion and dismissal of personnel and relationship developed between the area of operations with internal and external entities to the port.
Thus, in characterizing the day-to-day process of decision-making linked to productive capacity, the existence of two main ways of configuring these decisions, which lie in "routine" and "strategic" decisions, is identified. Such decisions arise from the management of the port productive capacity, having some points of interaction and convergence, however, differentiating themselves through the way in which they are processed and under what conditions they occur.

Routine Decisions

Decisions of productive capacity called “routine” refer to those of the day-to-day operation of the port, so that activities are not interrupted, and there is full continuity, given that port work, happens day and night, every day of the week. The more efficient and effective the performance of the operations as a whole, the better use the operations manager will make of the port capacity, reducing the operating time and, consequently, the dwell time of ships, since it constitutes a critical factor and predictor of performance, as expressed by Interviewee F:

> So, that made us have the performance result impacted because they [the workforce] made ship stoppages, and then, thinking about the ship, it's not a R$ 1.99 business. Each hour of the ship is at least a thousand dollars. A thousand dollars to the exponential of R$ 3,20, this is almost three and two hundred, three and five hundred thousand Reais per hour, not programmed and not justified.

Therefore, routine decisions are linked to the activities of mooring and departure of ships, loading and unloading of goods, maintenance of equipment and, yard and warehouse organization, as reported by one of the interviewees: "(...) every day I always have a decision to make. From a decision, so to say, more operational, which is linked to production. For example, in my area I am responsible for the shipping area, that is, it is the area that is constantly entering and leaving ship, then it is the area that involves the entry and exit of ships (Interviewed C)”. These activities are interconnected, and all are part of the port's business processes, which allow the work to be performed and delivered to the customer.
Also, such decisions are predominantly configured based on rational and analytical decision-making, especially when there is no occurrence of atypical event in operation. Managers generally make massive use of decision support systems, especially those based on information technology (e.g., SGP, OCP, Arena, TAG, Log One, Loud Sister, Navis, Totus, and others). Which extract data and information to guide their decision-making processes. For this, it was observed the need for teams with analytical skills, capable of transforming this data into accessible and applicable knowledge in decision making, since they indicate what is best for the operation regarding productive capacity. Also, the respective decisions have a shorter temporality, that is, take less time to be taken, mainly because routine activities are mostly standardized, precisely to avoid interruption of operations that generate negative impacts on

port operations. The fact that the activities follow a pattern facilitates the agility, precision, and reliability of the decision:

> When I say so, to the maximum I surround myself with data, obviously when they are take-up situations, that's it here and everything else, the decisions are very automatic, because the results are around: 'look, if we do not put a second truck here, maybe we will not achieve the productivity that we are planning and that is necessary to conclude the contract. I'm going in with another truck. Go firm, that's settled. Because we're losing performance, it's not going to cost us anymore. Keep going'. This is a kind of operational decision. Quick and practical within what people are stipulated (Interviewee D).

However, the decision-making reality is also identified in the context of uncertainty, risk and time pressure, considered as unwanted in routine operations. A typical example of occurrence is in Interviewee D's account: "Then the ship is planned to berth at night, then it's late, and then you have to make the decision not to buy labor, reverse plan, change operations drawings and everything else because they are part of the routine line". When decisions need to be configured in abnormal operating conditions, managers end up supporting their decisions in a decision-making process considered intuitive, that is, resort to their tacit knowledge, your experience, the lessons learned, and your feeling/emotion, taking them as drivers of the decision-making process. Also, depending on the complexity of the problem that needs to be addressed, they also rely on the intuition of the work team.

The use of intuitive processing in routine decision-making can also occur when software or IT systems fail, insufficiency and/or lack of data, the emergence of unforeseen situations that compromise the operation - as reported above - and sometimes, as a complement to the rational decision-making process. It is worth emphasizing that when this decision becomes the 'guiding thread' of decision, this more intuitive decision-making process usually emerges more based on the experience of the operations manager or his team. That is, encompassing cognitive elements related to "tacit knowledge", to "memory", to "pattern recognition" and to "parallels".

> So, the system that makes wave measurement for us, in constant high waves, it often has problems, it stops emitting. So they have to have a B plan, and the B Plan is a redundant system that we have, but they do not give all the information. So they have to use the experience of these professionals, which I told you are ship commanders that sailed in all the oceans, use their experience because he looks at the moon and looks at the sea and knows what will happen. It's like a fisherman. So we use the experience of these professionals to make a decision. And many times, in their trajectory, they have made a decision [...] there is one who is sixty years' old who traveled in these oceans with large ships in a much worse condition and without information and technology. So we use this expertise to make decisions (Interviewee E).

Generally, such a decision-making process has a shorter temporality, that is, as the decision-maker triggers recognizable blocks of knowledge stored in his memory, the decision is configured very quickly, almost automatically. Hence the prevalence of its use in situations where time pressure is high, or in conditions where risk and uncertainty are dominant and require responsive responses. However, although managers recognize the use of intuition and its importance in the decision-making context, mainly because port operations are very sensitive to changes in climatic and maritime conditions, it is worth noting the value of pre-planning as a coping strategy for minimization of risk and elimination of uncertainty. This situation occurs from the support of information technology, data and information and people with analytical capabilities, as pointed out by Interviewee A: "I highly value pre-planning, especially when it needs to happen, I try to minimize the risk a lot and eliminate uncertainty with this pre-planning".

Strategic Decisions

Nonetheless, productive capacity decisions are defined here as “strategic”, inherent to decisions that reflect the high impact on the port enterprise in the medium and long-term, mainly regarding performance results. These decisions relate to the purchase and rental of machinery, outsourcing of services, permanence, and termination of contracts, compliance with new regulatory requirements, reorganization of port functions and activities, customer service, contracting, promotion and dismissal of personnel - because the workforce is highly specialized and technical - and a relationship developed between the area of operations with internal entities (other functional areas) and external to the port (Navy, maritime pilotage, environmental and regulatory agencies, unions, etc.).

> So, for example, we are now making an assessment: it has certain service that is done by Vale people, Vale employees, but we are doing some internal analysis that, in the long run, this type of service becomes more expensive if I keep doing it with self-employees. If I outsource this service, I start to do this service with these outsourcers, in the early years this seems to cost more, but over time this cost will decrease, and the company will save money in the long term, i.e. based on that analysis, in this evaluation, everything would take that our decision will be to stop doing this service with Vale itself, and to start hiring someone to do it. In the long run, this gets cheaper.

In strategic decisions of productive capacity, decision making is configured from both rational and intuitive processing. What defines which type of processing is dominant is the matter upon which it is being decided. Decisions involving the purchase and rental of machinery, outsourcing of services, permanence and termination of contracts, compliance with norms and laws, as well as the reorganization of port functions and activities, for example, is the pre-eminent presence of rational processing, in the analysis of data and information coming from both information systems, staff, functional areas and company meetings. The analytical behavior of the manager gains evidence, since he carries out studies and deep investigations in line with the great planning and, assessments before decision-making.

Also, they tend to surround themselves with data and facts, when they have the time to think and decide. The predominance of rational processing mainly occurs because of the high financial impact that such decisions have on the business and the need to develop feasibility and risk analyzes, as well as the preparation of plans to prove to its peers and superiors the consistency and robustness of the decision that was chosen to pursue. This reality can be verified in the following section:

> (...) This was a fact that happened, (...), we had to invest in records of trucks through optical reading, which is an item called OCR here, an acronym. This is a decision that requires investment, so besides the investment, it's a legal service, that alone sells itself: 'Oh, I need to take legal action.' Just to keep a structure of this I needed to redesign my current operations designer. Who made this? The technical level. What did I do? Based on the technical drawing, I took the technical solution and the regulation solution with three or four investment options for decision making together with my top manager (...) (Interviewee F).

However, decisions that include customer service, recruitment, promotion and dismissal of personnel, as well as the relationship between the area of operations with internal and external entities to the port, are based primarily on elements of the intuitive decision-making process. These decisions include the use of the “feeling”, “impression”, and “affection”, denoting intuitive processing based on emotion. Recurrently, the use of a "relational" or "affective intuition" their decision making, need to articulate interpersonal relationships with the actors involved in different moments of the decision process.

> [...] but when the decision is linked to the human assets of the companies, which are the collaborators, the employees, then the emotion bias it enters. For example, if the person failed, I should train or punish. Training would be interesting to me. Punish, another possible way. But you eventually put your emotion there and say, 'I will not punish because I do not know, I think I'm going to shake him, the emotion of him being beaten'. So, there's no way you do not use the emotion; I'd say you even use it when you do not have it (Interviewee E).

Also, the use of intuition can emerge when the decision maker needs to deliberate on a strategic issue in a short period, in which the pressure of the time itself can cause risks to the maintenance of the installed productive capacity. From behavioral point of view, it is seen that time pressure tends to make the operations manager make decisions based on intuitive elements. Also, they select riskier ways of acting when they think that the expected consequences of their decisions may be positives, while the same time pressure can drive them to make less risky decisions by understanding that the expected outcome tends to be negative.

DISCUSSION OF RESULTS

The research findings show that the daily decision-making process linked to productive capacity is based on routine and strategic decisions, which are driven by rational and intuitive processing, in which operations managers use analytical and intuitive elements to outline their decision-making processes.

Decisions that were taken primarily by a more rational orientation, characteristically demonstrated that they were delineated in a deliberative, structured and quantitative way. Based essentially on logical mental processes, in which decision-making followed an orderly logical sequence (Simon, 1987), supported by a wide range of technological tools operated by individuals with analytical capabilities necessary to apply the knowledge generated from treatment of data and facts in the daily decision processes (Sincorá, 2016).

At the same time, decisions that received more intuitive contours presented themselves in two ways: one based on the experience of the manager and his team and another based on the manager's emotional and emotional elements. The most intuitive decision-making was routinely employed in atypical situations in which 'stress phenomena' were configured, such as time pressure, risk, and uncertainty (Carter et al, 2007, Sayegh, Anthony & Perrewe, 2004), induced by climate and maritime changes. In this research, the presence of such contextual variables led the manager to direct his or her decisions based on experience, accessing information stored in memory, represented by frozen analyzes habits and the ability to respond quickly through recognition.

On the other hand, the face-to-face interactions and interpersonal relationships developed by the operational manager with internal and external entities to the port during the design of the decision-making process worked as a 'trigger' for a more 'relational' and 'affective' intuition emerge motivating the manager to decide based on emotion. Simon (1987) points out that intuition based on emotion is very different from intuition motivated by experience (training and tacit knowledge). The behavior of the manager motivated by the emotion is a response to more primitive and instinctive impulses, being able to generate satisfactory results or not, like any other decision contour.

Although it was possible to identify decision-making processes that are relatively rational or more intuitive in both routine decisions and strategic decisions, there is a common presence of both rationality and intuition as drivers of the decision process. In this way, it can be affirmed that there is no "pure" and "ideal" type of decision making that is more adequate. In fact, what

exists are variations of this relationship, that is, rational and intuitive. One being more clearly used, and another depending on the type of decision-making (whether routine or strategic) and the type of context in which (e.g., under pressure of time, risk, or uncertainty), as corroborated in the studies of Agor (1986) and Shapiro and Spence (1997).

Thus, it is assumed that this relationship is inseparable and the combination of these can make the decision-making process and its results richer and contribute to the maintenance of productive capacity. This is consistent with the assumptions of Simon (1987), which states that the manager's experience involves the use of both types (rational and intuitive) in decision-making. In addition, Hodgkinson and Sadler-Smith (2003) argue that the maximum ability of the current organizations is in their individuals to be able to alternate between “mental habits” and “active thinking” in the construction of their decision processes.

From the speeches of operational managers, it is understood that one of the challenges experienced by them in their decision-making realities is in the balance of this configuration, even though it is something subtle and difficult to recognize on their part. They labeled themselves as “essentially analytical and rational” because they understand that more intuitive decision-making does not result in the best available solution to any business problem they face in terms of productive capacity and because they believe that it is not suitable for a context characterized by high technical, specialization of labor and standardization of activities (Serra, Martins & Bronzo, 2009; Zampirolli, 2017), as is the port. However, it was detected that managers, in their routine work, are at all times employing intuitive aspects in the delineation of their decision-making processes, whether as drivers or complements of analytical and rational processing.

Thus, decisions made through "rational-intuitive" processing are those that can provide adequate conditions for managers to make both routines and strategic decisions in their complex decision-making realities. What explain this affirmation is that the combination of analysis data and facts that run on software and IT systems and interpreted by capable employees, together with the use of expertise, the feeling and experiences of the managers, can provide a breeding ground for different possibilities for decision-making settings to be articulated intelligently by the professionals interviewed, with a view to improving their managerial decision-making related to productive capacity.

CONCLUSIONS

The main objective of this research was to understand how it is set up the day-to-day decision making process related to productive capacity, given the huge amount of data and information available in organizations. Based on the proposal, six semi-structured interviews were conducted with operational managers from the port area, distributed by six Brazilian coastal ports. Based on the data, it was possible to show among the findings of the research that the daily decision-making process linked to productive capacity is based on routine and strategic decisions and is guided by rational and intuitive processes.

Nevertheless, it was identified that although the port productive capacity decisions are divided into routine and strategic, it is verified that in both there is the presence of both rationality and intuition as “triggers” of the decision. In general, there is a relationship of interaction and complementarity between these processes, demonstrating that in the investigated decision-making reality interviewed managers combine in different ways “mental habits” (intuitive load) and “active thinking” (rational load). The construction of these decisions is considered as a maximum capacity in terms of decision making in today's corporations, especially for the possibility of making the decision-making process richer and more contributory.

Among the contributions of the study is the development of the proposal within a locus that is little investigated. It is not vast in the national scientific literature, studies that are dedicated to investigating the Brazilian port reality. In this way, with the realization of the research, it became possible to characterize part of the port environment, as well as to understand how the operational managers configure their productive capacity decisions, which in turn, are important for the continuity of operations, customer service and reach of results. Also, the segment investigated has social relevance, given that among its main functionalities is the transport and movement of goods necessary to society.

Theoretically, this article allows us to advance in the discussion of how the interrelationship between rational and intuitive decision-making in normal working contexts and under the influence of "stressor" variables - time pressure, risks, and uncertainties. Although many provocative ideas about the interaction between rational and intuitive decision making have been suggested in the literature, empirical and qualitative research in the field, particularly in the field of management, remains insufficient.

Therefore, the results of this research provide significant evidence of relevant associations between rational and intuitive decision-making process. However, limitations of the study can be woven, such as the failure to satisfactorily fill one of the articulated gap, related to the non-vigilance of the Decision Making literature for the development of theories under decision-making contexts related to risk, uncertainty and time pressure. Although they have been shown in the results, the contribution to this aspect still lacks more robust investigations.

For future research, it is possible to delve deeper into the discussion about how the decision-making process, in fact, is specifically delineated under crisis contexts, time pressure, risks, and uncertainties, especially in different decision-making realities. Also, it is recommended to analyze how the decision-making configuration (rational and/or intuitive) determines the result of the decisions taken, considering the influence of the analytical capabilities and the manager's experience.

ABSTRACT

Many organizations are attempting to implement business analytics solutions without addressing the issue of individual end user abilities and capabilities. We use previous structures of other orientation types to build and test the construct of Individual Analytics Orientation and its relationship with decision quality in both performance results and cognitive dissonance. University students from France, USA, Brazil and Slovenia are used to develop and test the measures and examine the relationship to decision quality. The results provide three independent constructs, a set of validated measures to use in further research and statistical validation of the relationship to decision performance.

KEYWORDS: Business analytics, analytical orientation, decision quality

INTRODUCTION

Many organizations are attempting to implement business analytics solutions without addressing the issue of end user abilities and capabilities. Analytics have the potential to transform the way organizations make decisions (Sharma, Reynolds, Scheepers, Seddon, & Shanks, 2010) but the implementation of analytics is a challenging initiative (Lukman, Hackney, Popovič, Jaklič, & Irani, 2011).

The complexity of businesses today means that a company needs to perform a considerable analysis of data gathered in vast quantities on a regular basis (Azvine, Nauck, & Ho, 2003). This makes it necessary to start using advanced analytics to analyze structured and unstructured data from both within organizations and from its environment. Analytics are not the technology in and of itself, but a group of tools used by people with skills and motivation to acquire information, analyze it and predict the outcomes of problem solutions (Bose, 2009).

Organizations are getting very interested in how to exploit analytics in decisions and how analytics can be used to leverage process improvement. The objective on exploiting analytics is to make the decision making process faster, more reliable, more consistent, and more aligned with the strategy and operations of the companies.

The available literature largely focuses on anecdotal case studies (DAVENPORT, 2006), statistical analysis of the impact of analytics (Trkman, McCormack, de Oliveira, Ladeira, & Oliveira, 2010) and the hype in the professional press. This is clearly important, especially in the initial, exploratory phase of the research of the impact of analytics. However, it gives little guidance about the factors that lead to the outcome of analytics implementation; a change in decision-making and consequently performance.

Davenport (DAVENPORT, 2006) mentioned “Analytical Skills” as the first action step for organizations to obtain analytical competition. He used the expression “Begin to build analytical skills”, which means that it’s often difficult to find individuals with some important requisites like quantitative and business skills. He has also mentioned that organizations should start looking for these requisites as soon as possible, and hire them in sufficient volume to create “critical mass”. How do you recognize these factors in individuals and recruit them to be analytical users?

A Gartner report (Tohamy, 2017) recommends that companies should train internal resources who lack formal data scientist training but exhibit a strong affinity for advanced analytics. One early and critical task for supply chain analytical leaders is to inventory their organization's current analytical talent. Tohamy (2017) recommends that they cast a wide net for these resources. In an age where technology is ubiquitous in our daily lives, many supply chain professionals have both the analytical proficiency and affinity to become effective analytical team members. Research shows that fewer than 20% of supply chain managers say they have excellent knowledge relative to supply chain analytics, while more than 45% say they have at most basic knowledge of this subject matter but suspect big differences among companies depending on the level of talent to manage these programs.

We propose that individual analytical orientation, or what you think about the topic of analytics, is an important concept that may be able to answer this question. Considering the high level of smart phone and computer use, if you are analytically oriented you will have developed analytical capabilities and you will value data and computing as a key part of your decision-making process.

The paper presents a construct and measure development effort that resulted in a validated set of construct and measures to be used in accomplishing this and can be used in future research.

The structure of the paper is as follows. First, the construct of individual analytical orientation (IAO) is developed. Then the measures are developed, tested and examined. The main findings and further research topics are set out at the end.

LITERATURE REVIEW

Davenport et al (2007) describe Analytics as the extensive use of data, statistical and quantitative analysis, explanatory and predictive models, and fact-based management to drive decisions and actions.

Davenport (2007) also mentions that a good analyst must have the ability to express complex ideas in simple terms and have the relationship skills to interact well with decision makers. Another example of an analytical profile was: “people with expertise in math, statistics and data

analysis who can also speak the language of business and help market their work internally and sometimes externally."

From a historical perspective, Briceland (1981) stated that Analytical skill is the ability to visualize, articulate, and solve both complex and uncomplicated problems and concepts and make decisions that are based on available information. These skills include demonstration of the ability to apply logical thinking, gathering and analyzing information, designing and testing solutions to problems, and formulating plans.

Others define Analytical skills as a manager's ability to use logical and scientific approaches to analyze problems and confront the business or to identify business opportunities (Goodman, Ladzani, Bates, de Vries, & Botha, 2005).

Considering that analytical skills are related to individual abilities, we understood it would be also relevant to explore the orientation of such individuals to properly use their skills/capabilities.

Organizational orientation can be understood as a set of socially complex thinking and learning processes that are unique, difficult for competitors to imitate, and resound internally throughout the organization (Barney, 1986; Hult, Ketchen, Adams, & Mena, 2008). In this sense, organizational orientation can be considered as strategic capabilities that are intangible and grows from complex cognitive behaviors that builds the basis for organizational strategic goals (Barney, 1986; RUSSO & FOUTS, 1997).

Managers who recognize the value in organizational orientations will develop them with the intent to positively impact firm performance (Mello & Stank, 2005; Noble, Sinha, & Kumar, 2002). Recognizing the need for analytics orientation and developing this is a critical focus of today's manager.

If you are analytically oriented then you should develop your individual analytical capabilities. Analytical capabilities may be conceptualized as an organizations ability to consolidate, analyze, and leverage its information resources to support its decision-making activities, enabled through cross-functional integration of processes and operations, people, and managerial capabilities (Plakoyiannaki & Tzokas, 2002).

Holsapple, Lee-Post, and Pakath (2014) offer that analytical capabilities are competencies possessed by an organization and its processors. Such capabilities determine what can be done in the way of evidence-based problem recognition and solving. It is suggested that analytical capabilities for managing evidence, using models, and logical reasoning can include: i) the use of techniques that are quantitative, qualitative, and combinations; ii) the use of statistical techniques; the use of systematic reasoning; iii) to work effectively with models that are: Descriptive/Explanatory, Predictive, or Prescriptive; and iv) to work effectively with evidence (e.g., databases, click-streams, documents, sensors, maps).

Most of the previous research e.g. (Holsapple et al., 2014; Mello & Stank, 2005; Noble et al., 2002) either explicitly or implicitly study analytical orientation/capabilities at the organizational level. We argue that, while important, this is insufficient. Everyone, regardless of their role in the organization, possesses a certain level of tool expertise and data processing capabilities which influences how he or she is inclined to use available data and information when making

decisions. The definition and measurement of Individual Analytical Orientation and Capabilities is therefore an important first step in the examination Organizational Analytical Orientation.

McCormack et al.	Individual analytics orientation construct and measures

THEORETICAL DEVELOPMENT/MODEL

This descriptive-conclusive investigated the relationships among variables and constructs of a conceptual model based on a quantitative effort relying on a typical structured process of investigation and data analysis. An initial phase was conducted in December 2017 using a group of (137), BS, MsC and PhD in Business Management candidates to assess adjustments to the data collection tool and group the measures into factors. The initial questions tested were developed through literature reviews and interviews and are self-assessment measures using a five point Likert scale. Factor analysis was used to group the measures into preliminary constructs.

The final data collection was executed in February 2018 at a triple-crown accredited business school in Slovenia. First year undergraduate business students were asked to fill out the survey before the start of the first computer lab of the Introduction to information systems course. The survey was translated into the Slovenian language by one of the researchers. The students completed the survey online using the school's computer to access the survey. Instructors were present to help with any technical problems. This assured the maximum participation of the students and avoided the non-response bias. Given the fact that we wanted to generalize our findings to the general non-specialist population of business users, the use of the student sample is justifiable (see (Compeau, Marcolin, Kelley, & Higgins, 2012)). After analyzing absent data and outliers, the final sample was collected and was composed of three hundred and seventy-one cases (371).

The final research model is based on three independent and two dependent constructs. The independent constructs are:
TTC – Tools and Techniques Capabilities (how capable are you with analytical tools)
IAO – Individual Analytical Orientation (how you use analytical data and models in making decisions)
DPC – Data Processing Capabilities (how you use data, critical reasoning and facts in making decisions)

The dependent constructs are:
HP – Hangover (regret about your decisions)
GP – Good Performance (self-reported decision performance)

Data Analysis – Construct Validation

We built the research model from theory then assessed the measurement models (reliability and validity) and the structural models (hypotheses). The common method bias in order to assure robust findings was also investigated. Figure 1 shows the model examined.

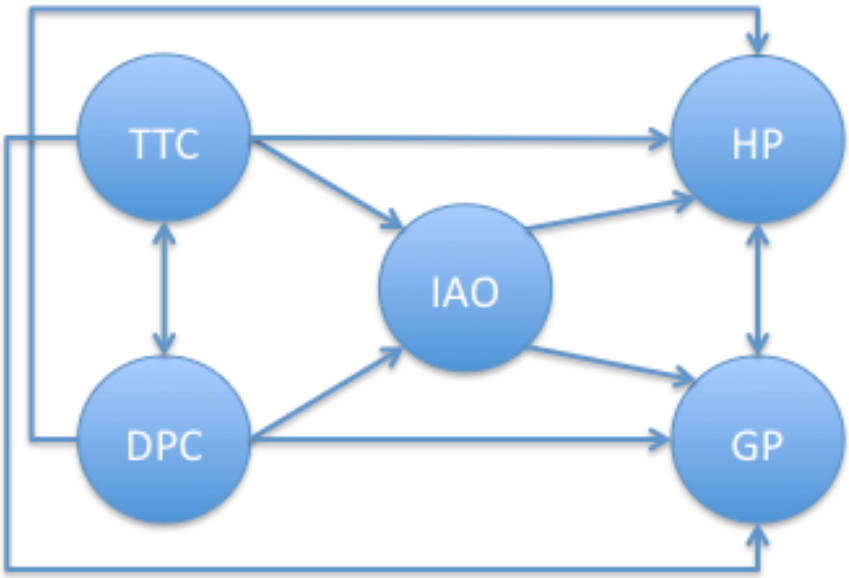

Figure 1: Theoretical Model

To analyze the results we used covariance-based structural equation modeling (CB-SEM) which assesses a new theoretical model (Fornell & Larcker, 1981; Gerbing & Anderson, 1988). Analyses were performed using lavaan: An R Package for Structural Equation Modeling (Rosseel, 2012).

Further, aiming to investigate the suggested relationships, the research model was tested. The goodness of fit of the model was determined using the ratio of chi-square to degrees of freedom (χ^2/df), the Comparative Fit Index (CFI), the Root Mean Square Error of Approximation (RMSEA) (Browne & Cudeck, 1992; Rosseel, 2012, 2014).

SEM comprised two components, which need to be tested separately: the measurement model (relationships between the concepts and their measurement indicators) and the structural model (relationships between all constructs).

Assessing the measurement model

We first assessed the measurement models with a confirmatory factor analysis, using maximum likelihood estimation with the lavaan. To access discriminant validity we used Heterotrait-monotrait (HTMT) ratio of correlation.

HTMT values close to 1, indicates a lack of discriminant validity. Using the HTMT as a criterion involves comparing it to a threshold. If the value of the HTMT is higher than .85 one can conclude that there is a lack of discriminant validity (Kline, 2011). Fornell and Larcker criterion and the assessment of the cross-loadings are inadequately sensitive to detect discriminant validity when compared with Heterotrait-monotrait (HTMT) criterion (Ab Hamid, Sami, & Mohmad Sidek, 2017; Henseler, Ringle, & Sarstedt, 2015). Thus, the use of HTMT criterion should be adopted for this purpose so that the interpretation of the causal effect in the modeling analysis is not misleading.

	HP	GP	IAO	TTC	DPC

HP	1				
GP	0.826	1			
IAO	0.123	0.573	1		
TTC	0.134	0.166	0.181	1	
DPC	0.352	0.443	0.302	0.325	1

Table 1: Heterotrait-monotrait (HTMT) ratio of correlation

As expected, the indicators all showed significant positive factor loadings, with standardized coefficients ranging from .143 to .739 (see Appendix). There were also significant positive correlations amongst latent factors with Good Performance (GP) and negative with Hangover Performance (HP) (see Table 2).

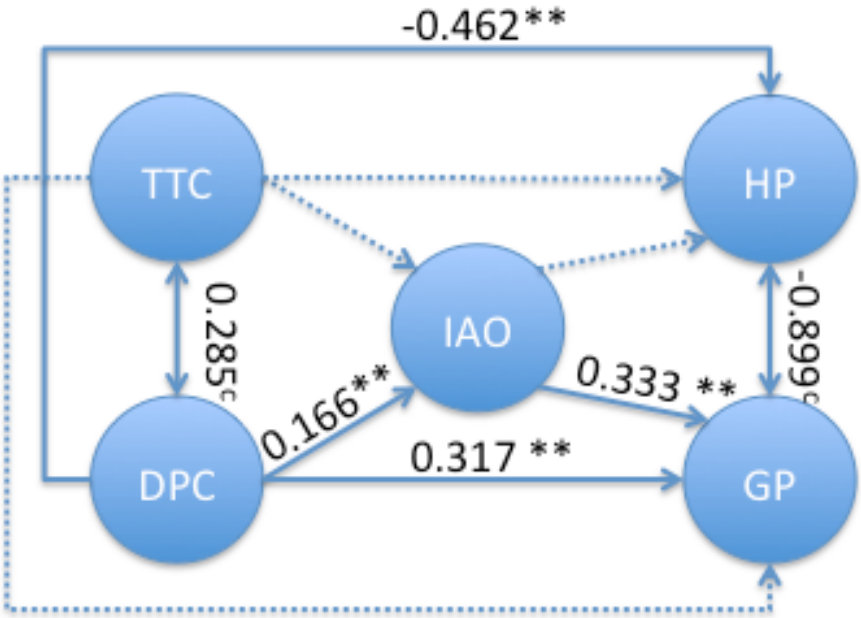
	HP	GP	IAO	TTC	DPC
HP	1				
GP	-0.844	1			
IAO	0	0.352	1		
TTC	0.034	0.077	0.126	1	
DPC	-0.37	0.329	0.185	0.285	1

Table 2: Correlations between latent variables

Converging normally after the 35th interaction, the model, shown revealed an adequate/close fit of the data, χ^2 = 530.027, df= 179, χ^2/df = 2.961, *p-value* = 0.000, CFI = 0.799, RMSEA = 0.073 [.066;.080], TLI = .764.

The CFA results indicated that the reflective items capture the underlying latent variables well and suggested a satisfactory level of convergent validity and internal consistency. Without exception, each item loaded on its hypothesized factor with a significant loading (all loadings significant at p<.001), thus supporting convergent validity.

To gauge the extent to which common method variance CMV might pose a problem, we compared our base CFA model with an extended CFA model which includes a single latent method factor that is uncorrelated with all other latent variables and that loads equally on all items (Podsakoff, MacKenzie, Lee, & Podsakoff, 2003). The results showed that the original model fits the data better than the model with a single latent factor. To compare both models in terms of their difference, we applied a chi-squared difference test that revealed a significant chi-squared difference ($\Delta\chi2$=712.29, p-value < 2.2e-16), suggesting that CMV is unlikely to introduce a substantial bias.



** p-value < 0.05
c covariance p-value < 0.05

Figure 2: Model Results

To test the hypotheses, regression equations were formulated and the respective betas were tested.

HP = -0.462 * DPC + Error

Data Processing Capabilities (DPC) was proven to be significant in explaining Hangover since more DPC would mean lower Hangovers. Individual Analytical Orientation (IAO) and Tools and Techniques Capabilities (TTC) were not significant to explain Hangover Performance (HP)

GP = 0.333 * IAO + 0.317 * DPC + Error

Individual Analytical Orientation (IAO) and Data Processing Capabilities (DPC) demonstrated a positive and significant relationship with Good Performance (GP) and Tools and Techniques Capabilities (TTC) were not significantly related with GP.

Individual Analytical Orientation (IAO) showed a significant and positive relationship with Data Processing Capabilities (DPC) but not significant with Tools and Techniques Capabilities (TTC). Despite of the fact of TTC showed no significant impact with other constructs of the structural model, a significant and positive covariance was shown between TTC and DPC. Additionally, a strong negative and significant relationship between HP and GP was identified. This result shows evidences that Hangover is higher when bad performance results are generated and vice-versa.

McCormack et al.	Individual analytics orientation construct and measures

RESULTS AND CONCLUSIONS

From this research, there appears to be validated constructs and measures for Individual Analytical Orientation and Capabilities with significant relationships to self-reported decision performance. The use of Data, Fact Based Decisions and the use of models and tools are all shown to be valid measures with relationships to Individual Analytical Orientation and Decision Performance. The capabilities that are validated in this research can be used to test the organizational readiness for analytics. This will identify what individual analytical capabilities are present or need to be improved to successfully implement an project of analytics. Hangover, or decision regret, was influenced by Data Processing Capabilities and negative Decision Performance. This makes sense. When you have less Data Processing Capabilities your Decision Performance generally decreases and you doubt your decisions (hangover). The use of data and models is a learned behavior driven by need or requirements. The importance of Individual Analytical Orientation became clear in this research with its relationship to Decision Performance but how do you develop this in individuals? This is a good area of future research with a research question of: How are Individual Analytical Orientation and Capabilities measured and influenced within an organization?

This was an investigative study and just the first step. Further research must be done on the organizational level to further validate these constructs and measures.

APPENDIX

Questionnaire

q1	I think that data is very important to my life.
q2	I make important decisions by analyzing data.
q3	I use analytical model (simple or complex) when making important decisions.
q5	I make fact based important decisions.
q6	I often use a Map App on my phone, iPad or computer.
q7	I often use "user reviews" (I.e. Yelp, etc.) when making an important decision.
q8	I usually search for data when considering an important decision
q9	I generally make good important decisions.
q10	I often must reverse course on an important decision because I was wrong
q11	I have confidence in my important decisions.
q12	I am often concerned about my important decisions (hang over) after they are made.
q13	If you were required, how easy it would be to: Find the right data to support your important decisions
q14	If you were required, how easy it would be to: Prepare the right data to support your important decisions
q15	If you were required, how easy it would be to: Exploit the right data to support your important decisions
q16	If you were required, how easy it would be to: Use tools (Ex: Excel, Power BI, Tableau) to describe what is happening
q17	If you were required, how easy it would be to: Use tools (Ex: Excel, Power BI, Tableu) to predict what is going to happen
q18	If you were required, how easy it would be to: Use tools (Ex: Excel, Power BI, Tableu) to prescribe what should be done
q19	If you were required, how easy it would be to: Make use of critical reasoning when making important decisions
q20	If you were required, how easy it would be to: Use evidences/facts to recognize problems
q21	If you were required, how easy it would be to: Use modeling techniques (i.e. Excel templates, etc.) to represent problems
q22	If you were required, how easy it would be to: Use modeling techniques (i.e. Excel templates, etc.) to solve problems
q23	What is your degree preference?

The Effect of Jumbling Multiple-Choice Questions on Exam Scores

John R. Dickinson
University of Windsor
Email: MExperiences@bell.net

ABSTRACT

Instructors may wish to administer multiple-choice examinations where the questions do not appear in the same order for all students. Against this, orderings of questions inconsistent with their order in the published bank (which generally follows the text content) may be disconcerting to students. Accordingly, the different orderings may serve to (dis)advantage students taking an exam with one ordering of the questions over students taking an exam having a different ordering of the same questions. The present research investigates the effect on exam scores of three different question ordering strategies.

KEY WORDS: Multiple-choice questions, Ordering questions on exams

The Effects of Man-Made Supply Chain Disruptions on Employee Job Satisfaction, Job Engagement, and Employee Productivity

ABSTRACT

The effects of a supply chain disruption on employees' job satisfaction and job engagement has not been given serious treatment in the operations management (OM) literature (Kleindorfer & Saad, 2005; Schmidt 2015). Other researchers in the organization behavior (OB) literature (Chen, Ployhart, Thomas, Anderson & Bliese, 2011; Judge, Heller & Mount, 2002; Judge & Kammeyer-Mueller, 2012; Riketta, 2008 among others) have investigated employee job attitudes in relations to supply chain disruptions or in general. However, despite this overwhelming body of work in OB and some discussion in OM, we still have a very limited understanding of the effects of supply chain disruptions on employees' psyche and firm performance.

KEYWORDS: supply chain disruptions; job satisfaction; job engagement; firm performance

INTRODUCTION

Employee engagement may seem like a frill in a downturn economy. But it can make a big difference in a company's survival. Gallup estimates the cost of America's(employees'?) disengagement crisis at a staggering $300 billion in lost productivity annually. When people don't care about their jobs or their employers, they don't show up consistently, they (either?) produce less, or their work quality suffers.

Amabile and Kramer (2011)

Supply chain disruptions, whether natural or man-made create operational and performance risk for the focal companies and their suppliers and can reduce shareholder value (Hendricks and Singhal, 2008). However, the question of how employees' attitudes, namely job engagement, job satisfaction change following disruptions remains an [un]der-researched phenomena. Moreover, subsequent to a man-made supply chain disruption, does the impact of the disruption

negatively affect employees' job attitudes and firm performance? Further, does the degree to which an individual identifies with an organization moderate the effects of a supply chain disruption on employee job satisfaction and job engagement? In this study, we assert that firms are better able to respond and recover from a disruption if they have engaged and satisfied employees. However, little attention has been devoted to understanding the impact of disruptions on employee outcomes. The extant operations management (OM) literature is replete with discussions about natural disaster disruptions and there is growing interest in man-made disruptions and their effects on companies' supply chains (Craighead, Blackhurst, Rungtusanatham, & Handfield, 2007; Kleindorfer & Saad, 2005; Schmidt 2015; Qi, Shen & Snyder, 2010; Van Wassenhove, 2006). In the majority of these studies, the firm, the supply chain, the supply chain partner or the shareholder is usually the unit of analysis. In this paper, we focus on the individual employee. Few OM studies, for example Haynie, Flynn & Mauldin, (2017); Jiang, Baker & Frazier (2009); Kolay, Lemmon, & Tashjian (2016) and Wangel (2012) have sought to understand the impact of companies' decisions on employees' job attitudes. Given the costs of a responding to and recovering from a disruption, we need a better understanding of the effects on disruptions on employees as firms seek to maintain resilience.

Organizational behavior researchers have devoted considerable discussion to the impact of employees' job attitudes on firm performance (Chen, Ployhart, Thomas, Anderson & Bliese, 2011; Ellinger, Ellinger & Keller, 2003; Judge, Heller & Mount, 2002; Judge & Kammeyer-Mueller, 2012; Riketta, 2008; Schneider, Hanges, Smith & Salvaggio, 2003). We still have a very limited understanding of the effects of man-made supply chain disruptions on employee outcomes, i.e. their job attitudes and performance. Given that disruptions are ubiquitous in the supply chain, the impact of this phenomena on employees' level of engagement and job satisfaction has important implications for scholars as well as practitioners (de Menezes, 2012; Sydow & Frenkel, 2013).

The current research applies contingency theory and social exchange theory (SET) to (state purpose of study in direct manner here) Past research has utilized SET to examine the buyer-supplier relationship, (Tanskanen 2015), organizational commitment, (van Kippenberg and Sleebos, 2006), and job embeddedness, (Hom et al., 2009). To the best of the authors' knowledge, SET has not been applied to discussions of job satisfaction and job engagement with respect to man-made supply disruptions. Specifically, we investigate two types of man-made supply chain disruptions: supply chain partner insolvency (SCPI) and labor disputes (LABDIS) and examine how these types of disruptions affect the job attitudes of those involved in that supply chain network and their subsequent job performance. Supply chain partner insolvency is regarded as a type of man-made supply chain disruption which interrupts or barges on operations at both the focal company and its buyer or buyers. Labor disputes are regarded as a type of man-made disruption that can occur at the focal firm or at any node in the supply chain network which can have a significant negative impact on firms' operations.

This study departs from previous discussions on job attitudes in the OM literature (see Jiang, Baker & Frazier, 2009; Agarwal & Gupta, 2018; Haynie, Flynn & Mauldin, 2017) to provide insight into the process through which employees' job satisfaction and job engagement affect their productivity. Job satisfaction is directly linked to productivity as well as to personal well-being (Aziri, 2011). Employee job satisfaction is related to employee job engagement in that both constructs describe the emotional experiences that employees derive from their jobs (Locke, 1976; Sari & Judge, 2004). Specifically, employee job satisfaction describes the pleasurable or positive emotional state resulting from the appraisal of the employee's job or job experiences (Sari & Judge, 2004) cited in Judge (1976). We explore these constructs in in an OM context under the conditions of a man-made supply chain disruption. Companies suffering the effects of a supply chain disruption want to minimize the impact on their ongoing operations. Employees are affected by these exogenous shocks to the company's operations. To the best of our knowledge, the degree to which these employees are affected through their level of job

engagement and job satisfaction has not been addressed in the literature. We address these issues in this study. Applying the foregoing theoretical framework, we address the following research questions:

RQ1. Do man-made supply chain disruptions directly or indirectly affect employees' work attitudes, specifically, job engagement and job satisfaction?

RQ2. Does the change in employees' job attitudes as a result of the disruption affect their productivity?

This study contributes to our understanding of man-made supply chain disruptions and the impact on employees' job attitudes. We utilize an integrated theoretical framework - combining Contingency and Social Exchange theories to gain a new perspective on this phenomenon. Man-made disruptions have not been explored to any degree in the OM literature relative to job attitudes. We extend the discussion by Haynie et al (2017) who focused on job engagement and its impact on employee task performance to highlight the impact of man-made disruptions in the supply chain. This study also has implications for practitioners seeking to understand how to maintain and improve employees' morale after the firm has experienced, either directly or indirectly, a man-made supply chain disruption.

The rest of the paper is outlined as follows: Section II provides the literature review, Section III provides theoretical framework and propositions; Section IV provides the discussion and implication; Section V provides limitations and future research directions; and Section VI concludes the discussion.

LITERATURE REVIEW

The supply chain is an interconnected network of interested parties where the decisions and strategies of one organization can influence the outcomes in other organizations along the supply chain (Wright & Kaine, 2015). That interconnectedness poses several kinds of risks for members of the supply chain. In their study, Jiang et al. (2009) discuss the operational risks posed by labor disputes, while Kolay et al. (2016) focus on the contagion effect distressed firms can have on the economic health of their rivals, suppliers, and creditors. Wengel (2012) suggests that one can assess the overall financial health of a business based on the demeanor of the employees. This suggest that companies' operations success or failure can have an impact on employees' affective states. This study investigates the impact of a disruption on the dyadic relationship between employees of the focal company or companies in the extended supply chain. Table 1 (see below) lists some of the various types of supply chain disruptions. These disruptions are not the only risks to the ongoing operations of an entity. In addition to exogenous shocks, research has indicated that certain management processes, e.g. Just-in-Time (J-I-T), Lean, and TQM (Total Quality Management) can have an impact on employees' job satisfaction, job engagement, and job embeddedness (de Menezes, 2010; Hom et al., 2009; Parker, 2003).

Other research had investigated the effects of other job characteristics on employee and firm performance. Lee et al. (2004) in their study noted that job turnover has been a major research topic in organizational studies for more than 50 years. In the current work, we highlight an area that has gone under-research during the same time frame – the effect of a supply chain disruption of employee's level of job satisfaction and job engagement on employee productivity and firm performance. Does a disruption create uncertainty among workers of the focal firm or an affected firm in the supply chain? And what can firms do to mitigate the effects on employees' job attitudes? Further, can firms predict a disruption and also work to mitigate its effects or prevent its occurrence? The level of satisfaction or engagement may be affected by other factors discussed in the literature, e.g. turnover intentions, level of commitment, etc. (Judge et al., 2012). Despite the extensive coverage in the literature, we do not understand the relationship between certain job attitudes and man-made supply chain disruptions and its attended effects on employee performance.

There is considerable discussion in extant literature on job engagement (Basit, 2017; Rich, LePine, & Crawford, 2010; Robertson, Birch, & Cooper, 2012; Shuck, Adelson, & Reio, jr., 2017; Vorina, Simonic & Vlasova, 2017). In spite of the extensive body of research in job engagement, there is still disagreement among academics and between academics and practitioners of what the meaning of the job engagement construct. Robertson et al. (2012) define engagement as "a positive attitude held by the employee towards the organization and its values." They note that an engaged employee works with colleagues to improve performance within the job for the benefit of the organization (Robertson et al., 2012). This expanded view encompasses job engagement and employee engagement. We focus on job engagement which, we refer to as an employee's cognitive, emotional, and physical investment in his/her work role to advance personal satisfaction and organization performance (Kahn, 1990; Robertson et al. 2012).

The relationship between job satisfaction, other job attitudes and firm performance has had much discourse in the organizational behavior (OB) literature (see Chen et al., 2011; Judge et al., 2002; Judge & Kammeyer-Mueller, 2012; Riketta, 2008) and operations management (OM) literature (see Jiang et al., 2009; Agarwal & Gupta, 2018; Haynie et al., 2017). Despite the extensive treatment in the literature, there is still little common ground on the causal relationship between job attitudes, e.g. job satisfaction and job engagement, and individual performance (Riketta, 2008). The relationship between those variables become more complicated when we introduce supply chain disruptions which occur infrequently but can have a significant impact on employees' job attitudes and ultimately firm performance. Moreover, there is concern about the stability of job satisfaction over time (Bowling, Beehr, Wagner and Libkuman, 2005). Although this gap in the literature exists, we won't be pursuing that line of inquiry here. However, it can be the focus of future research.

THEORETICAL MODEL

The arguments in this study rest on integrating two theoretical perspectives: social exchange theory and contingency theory. We examine two types of relationships in this study: the dyadic relationship between the employer and the employee, and the relationship between the firm and its operating environment, i.e. its supply chain. Following the literature, e.g. (Cropanzano & Mitchell, 2005; Emerson, 1976; Hom et al., 2009), we propose that these relationships are conditioned upon a mutual exchange. Cropanzano & Mitchell (2005) noted that workers can form distinguishable social exchange relationships with their immediate supervisor, coworkers, employer, and suppliers. By extension companies can form mutually beneficial relationships with other partners in the supply chain. Emerson (1976) noted that "social exchange is limited to the actions that are contingent on rewarding reactions from others." However, as Tanskkanen (2015) argued, "exchanges take place within structures of mutual dependence" (p. 580). There are power dependency issues in any relationship. In a supply chain, a monopoly supplier can exert power over a dependent buyer. Concomitantly, a distressed supplier can also exert power over a dependent buyer. The establishment of social exchange relations requires making investments that constitute commitments to the other party (Blau, 1964). This requires a level of trust. We extend the level of trust that should exist between a buyer and a supplier to an employer and an employee. Wang, Craighead & Li noted that disruptions can damage trust in the buyer-supplier relationship. We assert that the level of trust between an employer and employee can be affected by a man-made supply chain disruption which can negatively affect an employee's level of job satisfaction and job engagement. Employees at a company experiencing a disruption may be more concerned with whether they will be continued employment and more likely to experience lower job performance. The level of trust also extends into the supply chain. There is or should be a level of trust between supply chain partners to reduce anxiety and maintain a level of performance.

Organizations seek to maintain fit with their task environment (Thompson, 1967). We apply Van de Ven et al. 2013 logic that contingency theory may be applied to supply chains to understand changing economic and social environments (Van de Ven et al. 2013: 398). Contingency theory posits that firms seek to maintain fit in their task environments (Donaldson, 2001; Lawrence & Lorsch, 1967; Thompson, 1967). The task environment consists of four major sectors: 1.customers (distributors and end-users); 2.suppliers (labor, capital, materials, equipment, and work space); 3.competitors (markets and resources); and 4.regulatory groups (government agencies, unions, and inter-firm associations) (Thompson, 1967). These four sectors mirror those one would find in a supply chain. Firm operating in a task environment can experience a number of contingencies. In our study, we focus on task uncertainty, environemntal change and task interdependence (Donaldson, 2001). Firms operating in a task environment also go through a process of differentiation and integration wherein they insure that the organization is best situated to the specific environment in which the firm operates (Lawrence and Lorsch, 1967; Scott & Davis, 2016). Disruptions in the firms supply chain create misfit. Firms seek to regain fit to return to normal operating equilibrium (Donaldson, 1987).

Proposed Research Model

In this study, we are examining the moderated effects of organization identification and the mediated effects of job attitudes (i.e. job satisfaction and job engagement) on worker productivity (i.e. job performance) relative to a man-made supply chain disruption. Moderation is concerned with factors that influence the strength and direction of the relationship between the independent and dependent variable whereas mediation is concerned with the causal effects of the antecedent variable on the consequence variable (Muller, Judd & Yzerbyt, 2005:852). We discuss two man-made disruptions: supply chain partner insolvency, and labor disputes. In the following sections, we describe the variables in the model which are presented in Figure 1 below and posit our propositions.

Supply Chain Partner Insolvency (SCPI)

Supply chain disruptions, whether man-made or caused by some natural disaster continue to be a significant concern for scholars and practitioners. These adverse events have cascading effects up and down the supply chain stream – what some authors have described as a 'contagion or spillover effect' (Kolay et al. 2016; Wang, Craighead & Li, 2014; Yang, Birge & Parker, 2015). Although there is general interest in the literature on the effects of a disruption on firm performance (Chopra & Sodhi, 2004; Craighead, Blackhurst, Rungtusanatham, 2007; Hendricks & Singhal, 2003; Kleindorfer & Saad, 2005) little attention has been devoted understanding the type of disruption and its effects on employees' job attitudes of either the focal company or affected companies in the supply chain. One type of man-made disruption is supply chain partner insolvency (SCPI). We regard a supply chain partner insolvency as a meta construct which incorporates supplier insolvency. Supplier insolvency has been discussed in the OM literature (see Bode, Hubner, & Wagner, 2014; Chopra & Sodhi, 2004; Zsidisin & Smith, 2005) focusing specifically on those entities that supply raw materials in the supply chain. We extend the discussion to include any supply chain partner whose insolvency can disrupt the supply chain. Much of the literature focuses on tier one or tier two suppliers. For example, in a given manufacturing industry, tier-1 suppliers are those companies that supply the manufacturer directly with components for the product. Tier-2 suppliers provide subcomponents to Tier 1 supplier (Jaber & Goyal, 2009). However, some firms produce services rather than products, and their insolvency can disrupt the entire supply chain. For example, when United Airlines filed bankruptcy in December 2002, the company's filing had a ripple effect across the global supply chain (The Guardian, 2002, The New York Times, 2006). If one conducts a search for 'supplier insolvency', one is likely to get more hits for 'bankruptcy' than the original search term. This is because these two terms are used interchangeably. However, insolvency is an accounting term,

i.e. liabilities are greater than assets; whereas bankruptcy is a legal term involving a process of reorganization or liquidation (Baymout, Chhattani, Helali, Ali & Jegatheesan, 2013).

Corporate failure or death is an intrinsic part of organizational and economic life (Bode et al. 2014). Supply chain partner insolvency (SCPI) and bankruptcy are examples of such corporate failures. Sometimes, the government may become involved to save an industry for larger macroeconomic reasons as the U.S. Treasury Department did in 2009 when it created the Supplier Support Program to stabilize suppliers in the fledgling automobile industry (Kolay et al., 2016). Most often insolvent companies seek protection from their creditors in the bankruptcy courts. Scholars have advanced a couple of approaches describing how companies can mitigate the risk of a SCPI. For example, Zsidisin & Smith (2005) argue that early supplier intervention (ESI) may reduce the risk of supplier insolvency. Wengel (2012) discuss several warning signs of insolvency, including: delayed or missed tax payments, tightened supplier credit terms, poor budgets, cash flow forecasts and business plans, and ageing of creditors increasing. Despite these warnings, companies are still victims of supply chain partner insolvencies and bankruptcies. These "shocks" can wreak havoc on a firm's operations and can significantly and negatively impact its employees.

Supply chain disruptions are costly events. These costs can extend to the firms' cost of capital, or reduction in market value. In their study of nearly 1000 supply chain disruptions Hendricks & Singhal (2005) found that affected companies earned a 30% lower return Companies should be proactive to mitigate these costs. However, as Babich, Burnetas, & Ritchken (2007) note, companies do a poor job of overseeing their supply chain networks.

The foregoing discussion has focused on the effects of supply chain partner insolvency on the affected firm, its supply chain partners, and its position in the market. There is no mention of how this type of disruption affects employees' level of job satisfaction and job engagement. There are power dependencies in any dyadic relationship. The relationship forged between and employer and employee can suffer if there is an external threat, i.e. a supply chain disruption, that undermines the relationship – the trust that exists in that dyadic relationship (Wang et al. 2014). We argue in this study that a supply chain partner insolvency will have a negative effect on those employees in the affected firm and will also negatively affect employees in that affected firm's supply chain network.

Labor Disputes

Although labor is a major cost in almost any business enterprise, it appears that the topic is almost never the subject of discussion until there is the possibility that companies may have issues with their labor forces. A quick search of Google Scholar using the term "labor disputes and supply chain disruptions" does not return many articles. The same holds dearth of informational searches holds for a number of other databases, e.g. Academic Search Complete, Business Source Complete. We found one article in the OM literature (Sydow &Frenkel, 2013) which had "labor" in the title. In their study, which focuses on the employment relationship in the supply chain, Wright & Kaine (2015:489) highlight some of the pressing labor issues: inferior wages and working conditions, precarious employment contracts, work intensification, work health and safety risks, and minimal investment in employee development. These issues relate to the contractors or subcontractors of firms in the supply chain. They do not address similar issues of workers in the focal firm or partners in the same supply chain. Other studies, especially in the economics literature, e.g. Gomez-Paredes, Yamasue, Okumura & Isihara (2015) also address labor directly. The majority of articles discuss labor in the context of risk. This is not so in the practitioner and business press (see Banham, 2009; Butler, 2015; Miller, 2015; MMR, 2015; Welshans, 2015). A review of the risk management literature (see Chopra & Sodhi, 2004; Chopra & Sodhi, 2014; Revilla & Saenz, 2014; Silbermayr & Minner, 2014; Tomlin, 2006) discuss labor risk in relation to the firm. None consider the impact of a labor dispute on

the job attitudes of the employees of the affected companies. This lack of scholarship highlights a significant gap in the literature. There is obvious concern for practitioners. However, researchers have devoted minimal attention to this phenomenon. This study addresses that lack of scholarship.

Given the foregoing discussion, this study posits that there is a negative relationship between a certain types of man-made supply chain disruptions (e.g. labor dispute and supply chain partner insolvency) and employees' level of job engagement and job satisfaction. Basit (2017) noted that employees' social environments make them feel psychologically safe (or unsafe in the case of a disruption) and the level of safety or unsafety influences the employees' willingness to invest cognitive, emotional, and physical energies in their work. Whether these environments allow employees to have a voice, i.e. express their concerns, can also have an impact on organizational goals, employee well-being, external stakeholders, and organizational performance (Knoll & Redman, 2015). Although firms may engage in work design and other ways to motivate employees, there is little evidence that firms are concerned about the negative effects on employees of external events that affect the firm. This study also asserts there is a negative relationship between the various types of man-made supply chain disruptions and worker productivity.

P1: *Man-made supply chain disruptions (e.g. labor dispute or supplier insolvency), are negatively associated with employees' job engagement such that employees who experience a man-made supply chain disruption will have lower job engagement.*
P2. *Man-made supply chain disruptions (e.g. labor dispute or supplier insolvency), are negatively associated with employees' level of job satisfaction such that employees of the company affected by a man-made supply chain disruption are more likely to have lower job satisfaction.*
P3: *Man-made supply chain disruptions (e.g. labor dispute or supplier insolvency), are negatively associated with employees' performance such that employees of the focal firm as well as other firms in the supply chain network who experience a man-made supply chain disruption will have lower performance.*

Organization Identification as a Moderator of Supply Chain Disruption Effects
Identity is defined in the literature as a "self-referential description that provides contextually appropriate answers to the question, "Who am I?" (Ashforth et al., 2008). Employees who identify with a firm are more likely to exhibit higher levels of job engagement. Organizational identification has been shown to relate positively to employee performance (Ashforth, Harrison, & Corley, 2008; Menguc et al., 2016). The degree to which an individual is associated with a firm helps to determine that individual's emotional state if the firm is affected by an exogenous shock. If the firm experiences a supply chain disruption an employee who strongly identifies with the firm is more likely to experience lower levels of job engagement than an employee who does not identify with the firm (Kreiner & Ashforth, 2004). Employees identification with a firm fulfils a psychological need. In their studies, Kreiner & Ashforth, (2004) as well as Ashforth et al., (2008) address the affective state of employees who identify with a firm. Employees who exhibit a psychological linkage to a firm have been shown to experience varying levels of job satisfaction, work engagement, absenteeism, turnover intentions, citizenship behaviors and job motivation (Agarwal & Gupta, 2016; Knoll & Redman, 2016; van Knippenberg & Sleebos, 2006). In their study, Ashforth et al., 2008) regard identification as "the perception of oneness or belongingness to some human aggregate." The human aggregate under discussion here is the individual's employer. Based on the literature it follows that the more an individual identifies with an employer, the more he/she is likely to experience lower levels of job engagement if the firm experiences a man-made supply chain disruption.

P4. *Organization identification moderates the relationship between a man-made supply chain disruption and job engagement, such that this relationship is stronger for employees with strong organization identification.*
P5. *Organization identification moderates the relationship between a man-made supply chain disruption and job satisfaction, such that this relationship is stronger for employees with strong organization identification.*

Job Engagement and Performance

An employee's level of job engagement may be contingent on several factors. One of these factors is the job design. Agarwal & Gupta (2018) citing Hackman and Oldman (1975) noted that a well-designed job contained five characteristics: 1. task identity; 2.job autonomy; 3.job feedback; 4. task variety; and 5. task significance. Job engagement heightens the meaningfulness of work thereby allowing employees to focus on the task and exhibit higher levels of performance (Haynie, Mossholder, & Harris, 2016). Engaged employees feel a sense of connection to their tasks. These employees express themselves physically, cognitively, and emotionally in their job role performances (Chhetri, 2017). In their study, Haynie et al. (2016) utilized items from Rich, LePine, & Crawford (2010) to measure the three subfacets of employee engagement: physical, cognitive and emotional energies invested into work. Firms can create work environments that can engage employees and allow them to fully maximize their potential (Basit, 2017). Job engagement describes the process through which an employee identifies with a group or organization and invests his or her energies to meet the expectations of the entity (Haynie et al. 2016). This study argues that an employee's level of job engagement is negatively affected by disruptions in the firm's operating external environment.

Some scholars have examined the mediating effects of job engagement and various aspects of employee and firm performance (Agarwal & Gupta, 2018, Chhetri, 2017, Haynie, Flynn, & Mauldin, 2017; Haynie, Mossholder, & Harris, 2016). This study posits that an employee's level of job engagement positively mediates the impact of a man-made supply chain disruption on employee productivity. Man-made supply disruptions can have an impact of employees' dispositional states. Highly engaged employees should value changing deteriorating conditions, such as a man-made supply chain disruption (Knoll & Redman, 2016). It follows that employees' emotions and attitudes in response to environmental conditions can have an impact on their level of engagement (Haynie et al., 2017). Although companies focus on the internal environment to create the conditions for greater employee engagement, companies should also devote some energy to understanding those exogenous shocks, such as a man-made supply chain disruption that might impact employee engagement.

A reduction in an employee's level of engagement is likely to have negative effects on other outcomes, especially task performance (Haynie et al. 2016). These negative effects can also extend to firm performance – assuming, of course, that an engaged employee is indeed a productive employee. The link between job engagement and job performance is still a matter of some debate since much of the literature focuses on engagement as the polar opposite of burnout (Martin, 2017; Rich et al. 2010). Researchers have relied on the Maslach Burnout Inventory (BMI) to measure engagement (Martin, 2017). Following the literature, we offer the following proposition.

P6. *Employees' level of job engagement is positively related to employees' performance such that employees experiencing negative job engagement are more likely to experience lower performance.*
P7. *Employees' level of job engagement negatively mediates the impact of a man-made supply chain disruption of employee performance such that employees of a firm experiencing a man-made supply disruption will likely experience decreased job engagement which then leads to lower performance.*

Job Satisfaction and Job Performance

Whether job satisfaction influences job performance remains an unsettled question in the OB literature (Crossman & Abou-Zaki 2003). In their study, Wright, Cropanzano & Bonet (2007) citing Judge and colleagues noted that the relationship can be organized around seven models: 1. job satisfaction causes job performance; 2.job satisfaction is caused by job performance; 3.job satisfaction and job performance are reciprocally related; 4.job satisfaction is spuriously related to job performance; 5.the job satisfaction-job performance relation is moderated by other variables; 6.job satisfaction is not related to job performance; and 7.there are alternative conceptualizations of job satisfaction-job performance. Although Judge et al (2002) found support for the relationship between job satisfaction and job performance, Wright et al (2007) in their study estimated that other variables may moderate the relationship between the two variables. Our research supports Judge et al's (2002) contention. The strength of the relationship can be tested empirically. In their study, Judge et al. (2002) found the correlation to be 0.30.

An employee's level of job satisfaction can significantly impact other areas of his/her work life, e.g. commitment to the firm, quality of service provided to customers, self-efficacy or personal well-being; level of engagement (Crossman & Abou-Zaki, 2003; Carter, Nesbit, Badham, Parker, & Sung, 2016; Menguc, Auh, Katsikeas, & Jung, 2016; Wright et al. 2007). These areas either directly or indirectly relate to performance. In his study, Riketta (2008) found a significant, but weak relationship between job attitudes (job satisfaction and commitment) and performance. There was no support for the reverse relationship.

Job satisfaction is one of the most studied job attitudes (Riketta, 2008). Individuals exhibit some emotional attachment to their organizations and their work. However, whether or not there is a causal link between these two variables is the subject of much empirical investigation. In his study, Riketta (2008) found that job attitudes are more likely to affect performance than vice versa. This is consistent with other studies that have examined the relationship between job satisfaction and firm performance (see Chen et al., 2011; Hemalatha, Krisnaveni, & Deepa, 2015). In their study, Hemalatha et al. (2015) found a direct link between job satisfaction and firm performance. if "Happy employees" are indeed "productive employees" (Saari & Judge, 2004) understanding how to measure and influence job satisfaction is a critical factor for improved and sustained firm performance. Chen and colleagues note in their study that when job satisfaction improves over time, employees will be more motivated to stay with their current organization (Chen et al., 2011). Although these authors were interested in the relationship between level of job satisfaction and job turnover intentions, it is evident from their research that the level of job satisfaction is directly linked to firm performance. Other scholars have sought to explain the importance of job satisfaction. Ilies and colleagues examined the impact of daily job satisfaction on family work-life balance (Ilies, Schwind Wilson & Wagner, 2009), while Judge et al. (2002) investigated the relationship between job satisfaction and the Big Five personality traits. Ilies, Fulmer, Spitzmuller & Johnson (2009) also investigate the relationship between certain personality traits and job satisfaction. While, informative, these studies focus on organizations operating in the normal course of business. No treatment is given to firm experiencing a supply chain disruption and the effect a labor dispute or supply chain partner insolvency can have on the supply chain network. Filling this void is one of the goals of this study.

The relationship between job attitudes and firm performance has been examined to some degree in the operations management (OM) literature (Autry & Daugherty, 2003; Ellinger et al., 2003; Jiang et al. 2009). Some studies have examined how implementing certain management processes, e.g. Just-in-Time, Groebner & Merz (1994); Quality/Total Quality Management (TQM), de Menzes (2010); Rahman & Bullock (2005) impact employees' job attitudes. In her study on the relationship between implementing lean production practices and

employee outcomes, Parker (2003) found that work characteristics mediate that relationship. One key characteristic was employee job satisfaction. The "happy employee hypothesis', assumes that satisfied employees will exhibit higher levels of organizational commitment, less absenteeism, and be more productive (Autry & Daugherty, 2003; de Menezes, 2010; Saari & Judge, 2004). This assumption seems not completely borne out in the study by Groebner & Merz (1994) who found little statistical significance in job satisfaction between two groups of workers on some dimensions of job attitudes: those implementing Just-in-Time practices and those employees not implementing J-I-T. However, the authors did find support for the relationship between job attitudes and job performance on other dimensions. In a follow up study, the authors found that "changing to JIT had a positive effect on job attitudes" (Groebner & Merz, 1994). We expect that we will find a positive relationship between job satisfaction, job engagement and employee performance.

The results of Groebner & Merz's (1994) demonstrate the difficulties of understanding the relationship between job satisfaction, employee and firm performance. Nevertheless, we argue in this study that there is a relationship between the level of employee job satisfaction and job performance and by extension firm performance. Given the relationship between job satisfaction and employee performance, we offer the following propositions:

P8. *Employees' level of job satisfaction is positively related to employee performance such that employees experiencing negative job satisfaction are more likely to experience lower performance.*

P9. *Employees' level of job satisfaction negatively mediates the impact of a man-made supply chain disruption of employee performance such that employees of a firm experiencing a man-made supply disruption will likely experience job satisfaction and lower performance.*

DISCUSSION AND IMPLICATIONS

We are undertaking this study to examine the mediating and moderating effects of several variables on employee performance under the conditions of a man-made supply chain disruption. OM scholars have not systematically utilized the mediation process to examine the relationship between and among variables (Rungtusantham, Miller & Boyer, 2014). We examine two type of man-made supply chain disruptions: 1. supply chain partner insolvency; and 2. labor disputes. These types of disruptions have been addressed in the extant OM literature (Sydow and Frenkel, 2013; Samvedi et al. 2013; Yang et al. 2015). However, scholars have not advanced the discussion on the risk of these disruption and the effects on employee job attitudes. For example, Jiang et al (2009) discuss the operational risk of labor problems; the reputational risk of labor problems, and the supply chain risk of labor problems. The authors note that little is known about the factors that affect job attitudes of suppliers' laborers in developing countries (p.170). While we do not focus on developing countries, we assert that the disruptive nature of labor strikes can have impacts on various nodes in the supply network and can negatively affect employees' job attitudes. Further, although there is considerable discussion in the literature of the effects that distressed firms can have on the economic health of their rivals, suppliers and creditors (Kolay et al (2016). To the best of our knowledge, there is no discussion of the impact of the distressed company on the job attitudes of the firm's employees.

Companies facing financial distress also create problems along the supply chain. In his discussion of how to spot the signs of insolvency in companies, Wengel (2012) noted the demeanor of the staff provided an indication of the business' overall health. We assert that the job engagement and job satisfaction of employees pose a significant risk to their overall performance. We argue that the relationship between these two types of supply chain disruptions and employee and firm performance is mediated by the employees' level of job

engagement and job satisfaction. We also argue that the level of job engagement is moderated by the employee's level of organization identification. We do not address the relationship between the employee's commitment, i.e. level of identification with the organization and the level of job satisfaction. Future research should address this relationship in the context of a man-made supply chain disruption.

The "happy-productive employee" thesis continues to be debated in the literature (Cropanzano & Wright, 2001; Staw, 1986; Wright & Staw, 1999a, 1999b). We assert that engaged and satisfied employees will generally be more productive employees and this combination generally leads to greater firm performance. Much of the existing literature focuses on the mediating roles of job engagement and job satisfactions on job/task performance (Carter et al., 2016; Chhetri, 2017; Knoll & Redman, 2016; Rich et al. 2010; among others). Employees bring the full self in terms of physical, cognitive and emotional energies to the task and ultimately its performance (Rich et al., 2010). In a Marxian sense, there is no separation of the individual from his/her work. The individual commits to the task because there is a tacit understanding that the employer will not abuse the trust that exists in this relationship (Basit, 2017). This level of engagement and satisfaction leads to increased job performance.

Implications for Theory

This study integrates two theoretical perspectives: social exchange theory and contingency theory to examine whether man-made supply chain disruptions directly or indirectly affect employees' work attitudes, specifically, job engagement and job satisfaction? Further, does the change in employees' job attitudes affect their productivity and ultimately firm performance? Social exchange theory is useful in understanding the dyadic relationship between and employee and an employer. These relationships occur within a structured environment where workers can form distinguishable social exchange relationships with their immediate supervisor, coworkers, employer, and suppliers (Cropanzano & Mitchell, 2005). This study departs from the literature by examining how each of these relationships can be impacted by a disruption in the focal firm's supply chain. Extending social relationships to firms in a supply chain allows researchers examine the power dependencies that may exist. These relationships should serve the mutual interests of those parties. Often times, one party in the relationship dominates. Our investigation seeks to determine whether the power dependencies that exist in a structured environment also hold in a supply chain context and determine the moderating effects of organization identification on employees' job attitudes in the context of a man-made supply chain disruption.

The other theoretical perspective employed in this study is contingency theory. Following (Drazin & van de Ven (1985) and van de Ven et al. (2013), we utilize contingency theory to understand how firms respond to the changing economic and social environments in which they operate. Thompson (1967) noted that the task environment consists of four major sectors: 1.customers (distributors and end-users); 2.suppliers (labor, capital, materials, equipment, and work space); 3.competitors (for markets and resources); and 4.regulatory groups (government agencies, unions, and inter-firm associations). These sectors constitute the various nodes in a supply chain. We posit that the nature of the dyadic relationship that exist between firms in the supply chain may be a determinant in how the firm's employees respond to a supply chain disruption. We believe such relationships may enable the firm to regain fit with the operating environment. Disruptions create uncertainty for the firm operating in its task environment. We integrate these two theoretical perspectives to examine how the nature of the social relationship can reduce task uncertainty and increase task interdenepdence (Donaldson, 2001). This integration is a departure from how these issues are addressed in the OM and OB literatures.

This study examines the direct and indirect effects of a man-made supply chain disruption on employee job attitudes and employee performance. There is little theoretical or empirical evidence to support the link between job attitudes and employee performance. This

study seeks to establish a link between these two constructs. We also examine to effects of supply chain partner insolvency and labor disputes on the job attitudes of the employees along various nodes of the supply chain. Although practitioners are plagued frequently by these types of disruptions, these issues have not garnered sufficient interest in the academic community. This study may also engage OB scholars to investigate issues in operations management (OM).

Implications for Practice

Supply chain disruptions are an almost every day occurrence. Yet, companies seem ill-prepared to plan for and to manage various kinds of disruptions. Much of the existing literature focuses on supply chains as the unit of analysis. This study focuses on the individual employee as the unit of analysis. Managers can benefit from the analysis in this study and develop various strategies to help affected employees cope with the disruption. Firms may reduce operations and provide opportunities for training while they work through the disruptive event.

LIMITATIONS AND FUTURE RESEARCH

This study does not address employee engagement relative to job engagement in the context of a man-made supply chain disruption. Nor does it explore the relationship between job engagement and job satisfaction. We surmise that the relationship between these two constructs might have an impact on employee and firm performance. Employee engagement is a measure of an employee's positive or negative emotional attachment to their job, colleagues and organization (Vorina et al. 2017). Future research can investigate this relationship in the context of a man-made supply chain disruption. This study also does not address employee engagement relative to job engagement in the context of a man-made supply chain disruption. An employee's emotional well-being can be affected by a disruption which would negatively affect performance. We believe a future research would provide a greater understanding of this phenomena. Nor does it explore the relationship between job engagement and job satisfaction. We surmise that the relationship between these two constructs might have an impact on employee performance. Future research can investigate this relationship in the context of a man-made supply chain disruption.

CONCLUSION

This study seeks to examine the effects of a man-made supply chain disruption on employees' level of job engagement and job satisfaction and the attenuating productivity and firm performance. We argue that a disruption interrupts the normal processes within an organization and has an impact on the individual employee's psyche. The uncertainty created by the disruption may cause the employee to worry more about losing his/her job than about the company's stated goals. This uncertainty creates anxiety and may lead to reduced job engagement and job satisfaction. If one assumes that a happy employee is a more productive employee, it follows that an anxious employee will be a less productive employee.

DECISION SCIENCES INSTITUTE
The Efficiency Assessment of Renewable Energy Sources
with Data Envelopment Analysis

Umit Saglam
East Tennessee State University
Email: saglam@etsu.edu

ABSTRACT

In this paper, we compare the efficiencies of seven primary renewable energy technologies that generate electricity. We use Data Envelopment Analysis (DEA) to determine the most efficient renewable energy source with predetermined input and output variables. We apply four different analytical approaches to rank these energy sources with respect to their efficiency scores. According to our analysis, geothermal is the most efficient and solar thermal technologies are the least efficient renewable energy sources.

KEYWORDS: Data Envelopment Analysis (DEA), Efficiency Ranking, Electricity Generation, Multi-Criteria Decision Making, Renewable Energy Sources.

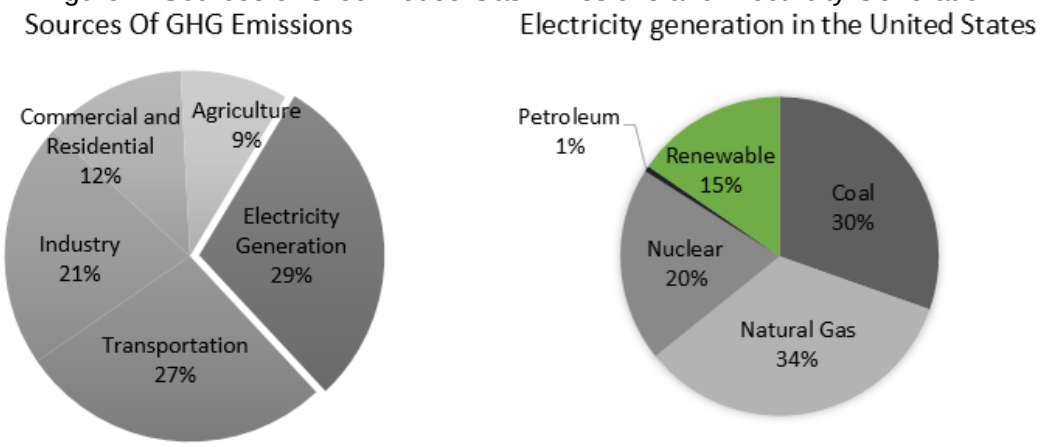
INTRODUCTION

Global warming is defined as the average temperature increase in Earth's surface, air, and oceans. It was first recognized by Fourier (1827), and Arrhenius (1897) developed the earliest model for the relationship between the temperature of the ground and carbon dioxide concentration. However, its perceived effects on human beings became more detectable and measurable within the last five decades. According to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC), the average global surface temperature increased by 0.85°C (1.53°F) since 1850 because of irrepressible increase of the concentration of greenhouse gasses such as carbon dioxide, methane, nitrous oxide, and chlorofluorocarbons. According to the IPCC the Fourth Assessment Report of the Intergovernmental Panel on Climate Change, if we will be successful to keep the level of the concentration of the greenhouses gasses constant, the global average surface warming would be about 0.2°C for a decade which may lead to severe problems in ecosystems all over the world. According to the scenario projections in this report, when the warming increases by 2°C, approximately 25% of the plant and animal species will be in danger of extinction. Also, crop productivity will decrease leading to food scarcity in many regions of the world. Millions of people will have health problems because of increase in malnutrition. Moreover, deaths, diseases, and injuries will increase due to severe weather conditions. Climate change also results in significant rising of sea levels; this will lead islands in Asia, Africa, and the Caribbean to become vulnerable to storms surge inundation and erosion. A rising on sea level also the cause of some islands will even vanish. The report adds that, by 2020, climate change will cause between 75 and 250 millions of people to have fresh water problems in Africa. Shortly, climate change would cause many severe problems if the global warming is not restrained. Not surprisingly, global warming and climate change become the most critical environmental and political issue between the countries. A total of 192 countries have signed the Kyoto Protocol, and 197 countries have signed the Paris Agreement, that aim to reduce the global average temperature to the pre-industrial levels by delimiting the production of greenhouses gas (GHG) emissions.

According to the Inventory of U.S. Greenhouse Gas Emissions and Sinks, the United States Environmental Protection Agency (EPA) reported that there are five primary sources of GHG emissions in the United States: electricity production 29%, transportation 27%, industry 21%,

commercial and residential 12%, and agriculture 9%. These values are consistent with the worldwide data of IPCC, where the electricity production contributes most to the total of GHG emissions. The U.S. Energy Information Administration (EIA) data shows that in 2016, 65% of electricity was generated by burning of fossil fuels (natural gas 34%, coal 30%, and petroleum 1%) which are the primary sources of GHG emissions for the electricity production. Only 13% of electricity in the United States, is generated by renewable energy sources, which produce a negligible amount of GHG emissions. Therefore, in this study, we focus on efficiencies of the renewable energy sources that generate electricity.

Figure 1: Sources of Greenhouse Gas Emissions and Electricity Generation



Renewable energy is produced and replenished by natural resources such as sunlight, wind, tides, and rain. There are five primary sources of renewable energy: wind power, solar, geothermal, biomass, and hydropower. Approximately, twenty percent of the total energy consumption is produced by these renewable energy sources and, the annual growth rate of the market share of the renewable energy since 1990 is about two percent (Owen 2004). According to Prindle et al. (2007), the synergies between energy efficiency and renewable energies are the twin pillars of sustainable energy policy that reduce GHG emissions. Therefore, in this study, we model a linear programming model to compare the efficiencies of these seven primary renewable energy sources that generate electricity. We evaluate the efficiency scores of each renewable energy source using Data Envelopment Analysis (DEA), which is a multi-criteria decision-making tool.

The remainder of this paper is organized as follows: Section 2, provides detailed literature review for DEA-related articles in the energy sector. Section 3, presents an overview of the DEA framework with the four different ranking approaches that we use in this study. Section 4, describes the model in detail with input and output variables. We also present each one of the renewable energy sources in detail in this section. Section 5, reports the results of each approach that we consider in DEA framework. Summary and concluding remarks are discussed in Section 6.

LITERATURE REVIEW

Data Envelopment Analysis (DEA), is a standard management tool for evaluating and improving the efficiency of both manufacturing and service operations. It was developed by Charnes et al. (1978). The DEA has been studied by a large number of researchers for various applications in: banking (Paradi and Zhu, 2013), education (Palocsay and Wood, 2014), environment (Goto et al., 2014), health (Kemp, 2015), and transportation (Zhou et al., 2014).

In the literature, there are more than thirty DEA – related articles for the energy sectors. Bagdadioglu et al. (1996) applied DEA to discover the relationship between privatization and ownership on the efficiency of Turkish electricity supply industry. Sueyoshi and Goto (2001) studied the performance of the electric power in Japan. Miliotis (1992) looked at Greece electricity distribution districts, Forsund and Kittelsen (1998) compared electricity distribution companies in Norway, by using DEA efficiency scores. Chen (2002) studied the cross efficiency of the electricity distribution sector in Taiwan, Pacudan and Guzman (2002) looked at the effectiveness of electricity distribution in the Philippines. Resende (2002) studied Brazilian electricity companies, and Korhonen and Syrjanen (2003) studied the efficiency of electricity distribution in Finland.
Boyd and Pang (2000) studied the linkage between energy efficiency and productivity in two segments of the glass industry. They compared the level of electricity and fossil fuel intensity by using regression analysis. They also showed that there is a strong correlation between energy intensity and productivity. Ramanathan (2001) applied DEA to the comparative risk assessment of eight different energy supply technologies. He concludes that solar photovoltaic and nuclear power are the most efficient energy sources. Jha and Shrestha (2006) used DEA to measure the efficiency of hydroelectric plants in Nepal. Chien and Hu (2007) apply DEA to the 45 OECD and non-OECD economies to determine the effects of renewable energy sources on the technical efficiency. They used macroeconomic data such as labor, capital stock, and energy consumption for the input variables where the real GDP served as the only output variable. They concluded that there was a positive correlation between use of renewables and technical efficiency and a negative correlation with the traditional energy. Jayanthi et al. (2009) applied DEA to U.S. photovoltaic industry. Cristobal (2011) applied DEA to evaluate the efficiency of the renewable energy sources in Spain. Kasap and Kiris (2013) develop an AHP and DEA approach to evaluate electricity generation companies of OECD countries. More recently, Chiu et al. (2016) compared productivity efficiencies of G20 countries by using DEA and Malmquist Index. Saglam (2016) compares the efficiencies of the eight primary renewable energy sources that generate electricity using four different analytical approaches. Saglam (2017a, 2017b) develop DEA models to quantitatively evaluate the relative efficiencies of the 39 states' wind power performances. Saglam (2017a) develops a two-stage DEA to quantitatively evaluate the relative efficiencies of the 39 state's wind power performances. Saglam (2017c) compare 236 large utility-scale wind farms' productive efficiency by applying two-stage DEA models. Saglam (2018) evaluate 95 large utility scale wind farms by using a two-stage data envelopment analysis and Tobit regression models.
In this study, we use DEA to compare the efficiencies of seven renewable energy technologies that generate electricity. We develop one of the most comprehensive models in the literature for this comparison. We apply four different approaches of DEA to rank relative efficiency of renewable energy technologies. The data is obtained from the most recent studies, which allow us to take into account any recent changes in these technologies. Also, cost function includes future projections as well. Therefore, the results of this study put some light on the future of these technologies for the policymakers.

DATA ENVELOPMENT ANALYSIS (DEA)

DEA is a non-parametric, multi-factor relative efficiency measure for evaluating and improving the efficiency of both manufacturing and service operations. Charnes et al. (1978) introduced the DEA framework to calculate the relative efficiency score with the division of the weighted sum of outputs and a weighted sum of inputs to obtain decision-making units (DMU). Equation 1 formulates the scenario where we have *N* number of maximized DMUs, which are obtained by *s* number of output and *m* number of input variables:

$$\begin{aligned} max \quad & E_e = \frac{\sum_{k=1}^{s} v_{ke} y_{ke}}{\sum_{i=1}^{m} u_{ie} x_{ie}} \\ s.t. \quad & \frac{\sum_{k=1}^{s} v_{ke} y_{kj}}{\sum_{i=1}^{m} u_{ie} x_{ij}} \leq 1; \;\; j = 1, 2, 3, \dots, n \\ & v_{ke}, u_{ie} \geq 0; \; k = 1, 2, 3, \dots, s; \;\; i = 1, 2, 3, \dots, m \end{aligned} \quad (1)$$

where E_e is the maximized efficiency score which belongs to the e^{th} DMU. Hence this set of equations can be easily converted to a linear programming problem by fixing the denominator to one:

$$\begin{aligned} & max \; E_e = \sum_{k=1}^{s} v_{ke} y_{ke} \\ & s.t. \;\; \sum_{k=1}^{s} v_{ke} y_{kj} - \sum_{i=1}^{m} u_{ie} x_{ij} \leq 0; \;\; j = 1, 2, 3, \dots, n \\ & \sum_{i=1}^{m} u_{ie} x_{ie} = 1 \\ & v_{ke}, u_{ie} \geq 0; \; k = 1, 2, 3, \dots, s; \;\; i = 1, 2, 3, \dots, m \end{aligned} \quad (2)$$

This linear programming formulation provides only two groups of results, efficient DMUs, and inefficient DMUs. Therefore we apply four different analytical approaches: (1) the benchmark ranking model, (2) the super efficiency model, (3) the cross-efficiency model, and (4) the virtual efficiency model, to find out the most efficient renewable energy source. Moreover, we rank all of the renewable energy technologies according to their cumulative efficiency ranking.

Benchmark Ranking Approach

The benchmark ranking method is one of the most popular ranking methods that focus on inefficient DMUs. This ranking method aims to improve inefficient DMUs with benchmarking of the efficient DMUs. The references are obtained by dual problem of the linear programming problem. The total number of references determine the rank of efficient DMUs. The most referenced efficient DMU ranks first, and inefficient DMUs rank equally.

Super-Efficiency Approach

Andersen and Petersen (1993) develop a super-efficiency approach for ranking efficient DMUs. In this method, linear programming problem is relaxed with omitting the unity constraint. This relaxation creates inefficient DMUs which are greater than 1, for initially efficient DMUs. Then the ranking is obtained by ordering these inefficient DMUs.

Cross-Efficiency Approach

The cross-efficiency approach, which was developed by Sexton et al. (1986), evaluates the performance of each DMU on the optimal input and output weights of other DMUs. Peer evaluation forms the cross efficiency matrix, and then the ranking is obtained by the simple average of each DMU's efficiency score.

Virtual DMU Approach

The virtual DMU approach was developed Golany and Roll (1994) by selecting the best values of each input and output variable. The original model is run one more time for each DMU by including new virtual DMU. After this process, virtual DMU becomes only efficient one, and the ranking is obtained in descending order of inefficient DMUs.

THE MODEL

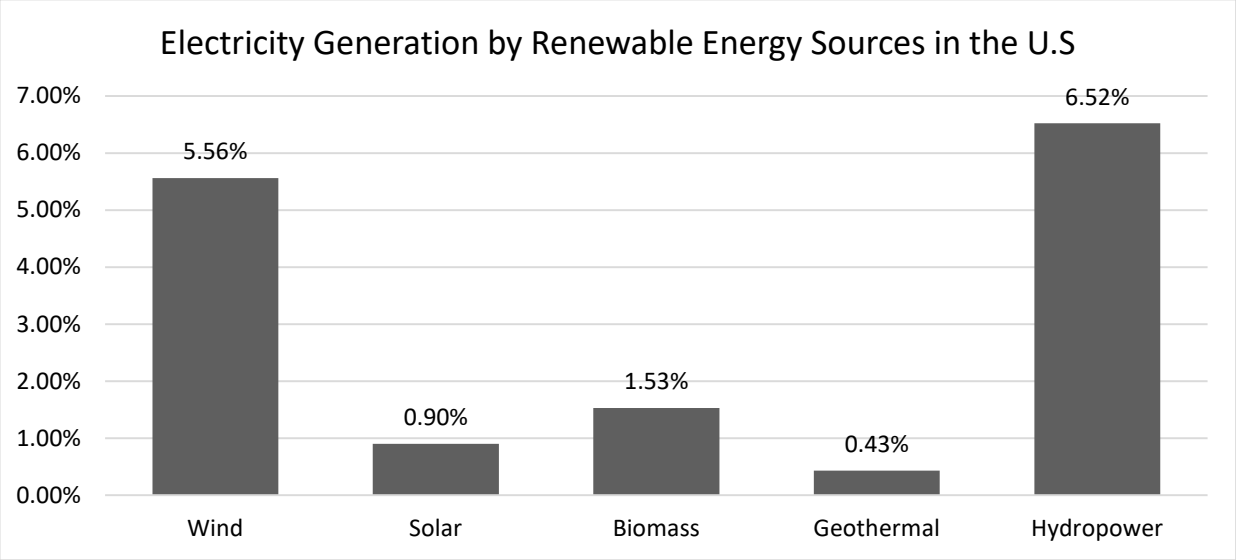
In this study, we want to rank the renewable energy sources by using pre-determined input and output variables. This study evaluates seven primary renewable energy technologies: Wind Power (both onshore and offshore), Solar Photovoltaic (PV), Solar Thermal, Geothermal, Biomass, and Hydropower. Only 15% of electricity in the United States, is generated by renewable energy sources and the distribution is shown in Figure 2.
In the next subsection, we look at each one of these renewable energy sources in detail. We also provide detailed information for each input and output variables in this section.

DEA Evaluations

Wind Power:

Wind power is one of the most expanded renewable and sustainable energy sources worldwide. According to EIA data, the entire installation of wind power is about 5.56 percent of the U.S. electricity supply. Electricity is generated by the conversion of kinetic energy of wind by using a wind generator. There are two types of wind farms that we consider in this study: An onshore wind farm is located on a land, where an offshore wind farm is located in the water.

Figure 2: Electricity Generation by Renewable Energy Sources in U.S.



Solar Photovoltaic (PV):

The solar photovoltaic technology generates electrical power by converting sunlight into direct current electricity. Although photovoltaic is one of the fastest growing power-generation technology, the entire installation of Solar PV supply is only 0.90 percent of U.S. electricity.

Solar Thermal:

The solar thermal technology generates solar power from solar energy by using solar thermal collectors. There are three major categories of solar thermal technology: (1) low-temperature collectors for heating and cooling systems; (2) medium temperature collector provides hot water

for both residential and commercial areas, and (3) high-temperature collectors for electricity generation.

Geothermal:

Geothermal energy is one the oldest renewable energy sources and is almost emission free. It is generated and stored in the Earth. Although the amount of geothermal energy is enormous, only a tiny fraction may be profitably exploited. Therefore, the entire installation of geothermal power is about 0.43 percent of the U.S. electricity supply.

Biomass:

Biomass is a widely available and naturally distributed renewable energy source which is derived from distinct energy sources like garbage, wood, waste, landfill gasses, and alcohol fuels. There are various applications of biomass energy such as direct burning, electricity generation, gasification, biofuels and anaerobic digestions to obtain heat, electricity, or another form (bio-fuel, biogas).

Hydropower:

Hydropower is both a renewable and sustainable energy source. It is derived from the force of falling or fast-moving water. Hydroelectricity is the most contributing renewable energy sources of the U.S. electricity supply. According to EIA data, the entire installation of hydropower is about 6.52 percent of the U.S. electricity supply.

The Inputs

In this study, we consider three input variables for the DEA analysis: (1) the total system levelized cost (TSLC), (2) land requirement, and (3) water consumption. Table 1 presents the related data, and Table 2 presents the statistical summary of variables for these input variables.
Total system levelized cost is one of the most critical input variables which combines different cost values: levelized capital cost, fixed and variable operations and maintenance expenditures, transmission investment and levelized tax credit. This data is obtained by EIA, Annual Energy Outlook 2016 Report. The cost function includes future projections for 2022 in this report. The TSLC of the renewable energy sources ranges between 41.90 $/MW (geothermal) and 179.90 $/MW (solar thermal). Land requirement is another critical input variable for this DEA analysis because some power plants require extensive land area, and some of them require none. Fthenakis and Kim (2009) studied life cycle land use of power sources. The data is obtained from this study. Water consumption is the last input variable for the DEA framework. This is also a critical input variable because some sources (wind and solar PV) are almost water-free during their operations, but some plants need an extensive amount of water for their operations (geothermal and hydropower) during their entire life cycle. The data is obtained from Fthenakis and Kim (2010), who studied life-cycle uses of water in U.S. electricity generation.

The Outputs

In this study, we consider four output variables for the DEA analysis: (1) the plant size, (2) the capacity factor of each power plant, (3) employment, and (4) greenhouse gas (GHG) emissions. Table 1 presents the related data, and Table 2 presents the statistical summary of variables for these output variables.

Table 1: Power Plants Data with Input and Output Variables							
	INPUTS			OUTPUTS			
	Input 1	Input 2	Input 3	Output 1	Output 2	Output 3	Output 4
Power Plant	TSLC ($/MW)	Land Req. (m^2/GWh)	Water Con. (L/MWh)	Plant Size (MW)	Capacity Factor (%)	Employment (1000s)	GHG Emis. (g/kWh)
Wind-Onshore	56.9	2410.0	8.0	1.0	40.0	88.0	16.0
Wind-Offshore	146.7	0.0	8.0	1.0	45.0	0.0	13.0
Solar PV	66.3	359.2	30.0	1.0	25.0	194.2	60.8
Solar Thermal	179.9	424.0	5462.5	1.0	20.0	14.6	39.6
Geothermal	41.9	206.7	26430.0	1.0	91.0	35.0	50.0
Biomass	96.1	488160.0	3775.0	1.0	83.0	152.0	88.0
Hydropower	67.8	25000.0	17000.0	1.0	58.0	8.0	20.0

In our framework, we use unit values for each power plant, so that the plant sizes are constant, and they are all equal to 1 for each renewable energy source. Capacity factor is the ratio of the actual output of a power plant and the total energy that plant would have produced at full capacity. The capacity factor of the renewable energy sources ranges between 20% (solar thermal) and 91% (geothermal). We obtained the capacity factor data from EIA's Annual Energy Outlook 2016 Report.

Table 2: Statistical Summary of Variables						
Variable	Description	Unit	Mean	Minimum	Maximum	Standard Dev.
Input 1	TSLC ($/MW)	$/MW	93.66	41.90	179.90	47.37
Input 2	Land Requirement	m^2/GWh	73794.27	0.00	488160.00	169373.71
Input 3	Water Consumption	L/MWh	7530.50	8.00	26430.00	9521.98
Output 1	Plant Size	MW	1.00	1.00	1.00	0.00
Output 2	Capacity Factor	%	51.71	20.00	91.00	25.25
Output 3	Employment	-	70.26	0.00	194.20	71.23
Output 4	GHG Emission	kg/MW	41.06	13.00	88.00	25.45

In May 2016, edition of the Renewable Energy and Jobs (Annual Review 2016), the International Renewable Energy Agency (IRENA) reported that in 2015, renewable energy industry employed 769,000 people in U.S. and 8.1 million people in all over the world. The employment data is critical output variable for this study because the contribution of each renewable energy sources varies almost in between 0 and 200,000. The data is obtained from this report. Lastly, greenhouse gas (GHG) emissions are the most significant output variable to find out the most efficient renewable energy source because they are the primary source of global warming and climate change. In this context, we use data from Amponsah et al. (2014), for GHG emissions of the renewable energy sources, and we incorporated it with taking the inverse of the actual values because it is the undesirable output of the operation.

DEA RESULTS

We model the linear programming problem for each one of the renewable energy sources by using the coefficients of input and output variables that are presented in Table 1. We solve these models with LINGO 16.0 which is a comprehensive software designed to build and solve linear optimization models quickly and efficiently.
Table 3 presents the DMU values of each renewable energy sources. According to Table 3, wind-onshore, wind-offshore, solar PV, geothermal, and biomass are efficient energy sources because they reach the maximum efficiency score, 1.0. On the other hand, solar thermal and hydropower are inefficient renewable energy sources because their efficiency scores are less than one. Solar thermal is inefficient because of high TSLC value, and hydropower is inefficient because it requires significant land area and high volume of water. According to these results, land requirement is a critical input variable for the efficiency scores of power plants. Although wind-onshore plant's TSLC is much less than wind-offshores', because of land requirement, both wind-onshore and wind-offshore reached the maximum efficiency score even wind-offshore does not create any employment.

Table 3: DEA Results for the Renewable Energy Sources

Power Plant	Efficiency Score	Efficiency	Inefficiency	References
Wind-onshore	1.0000	X		
Wind-offshore	1.0000	X		
Solar PV	1.0000	X		
Solar thermal	0.5115		X	2, 3, 5
Geothermal	1.0000	X		
Biomass	1.0000	X		
Hydropower	0.7876		X	1, 5

Table 3 also includes the reference sets of the benchmark ranking approach. As can be seen from Table 3, geothermal energy has the highest reference score because both of the inefficient energy sources referenced geothermal energy as the benchmarked energy source. High capacity factor and low TSLC makes geothermal energy source very preferable. According to this approach, wind-onshore, wind-offshore, and solar PV are referenced once. Therefore geothermal is ranked first and then wind-onshore, wind-offshore and solar PV share second highest rank, Inefficient
DMUs and biomass share the lowest rank according to the benchmark ranking method.
Table 4 presents the super efficiency and the virtual efficiency score of these seven different power technologies. For both of these two approaches, highest efficiency score refers the highest ranking, and then we rank the renewable energy sources in descending order. According to the super efficiency approach, solar PV has the highest efficiency score, which refers to the most efficient renewable energy source. Geothermal is ranked first for the virtual efficiency approach.
Table 5 shows the cross-efficiency matrix of these seven power plants. This is an *nxn* matrix where *ij* represents the efficiency score of a j^{th} power plant with the weights of the i^{th} power plant. The highest average efficiency score represents the most efficient power plant concerning its peers. According to these averages of these cross-efficiency scores, wind-onshore has the highest average efficiency score, which refers to the most efficient renewable energy source, and the solar thermal energy source is least efficient (or inefficient) renewable energy source according to the cross-efficiency approach.

Table 4: Super Efficiency and Virtual Efficiency Scores for the Renewable Energy Sources		
Power Plant	Super Efficiency	Virtual Efficiency
Wind-onshore	2.4154	0.7364
Wind-offshore	-	0.2856
Solar PV	14.7726	0.6320
Solar thermal	-	0.2329
Geothermal	5.8574	1.0000
Biomass	1.0876	0.4360
Hydropower	-	0.6180

Table 5: Cross-Efficiency Scores for the Renewable Energy Sources							
Power Plant	Wind-Onshore	Wind-Offshore	Solar PV	Solar thermal	Geothermal	Biomass	Hydropower
Wind-Onshore	1.000	0.265	1.000	0.102	1.000	0.719	0.524
Wind-Offshore	0.889	1.000	0.148	0.001	0.001	0.004	0.001
Solar PV	1.000	0.256	1.000	0.093	0.484	0.533	0.395
Solar thermal	0.246	1.000	1.000	0.511	1.000	0.001	0.026
Geothermal	1.000	0.437	0.536	0.144	1.000	1.000	0.662
Biomass	1.000	0.437	0.536	0.144	1.000	1.000	0.662
Hydropower	0.213	0.093	0.114	0.034	0.658	0.262	0.259
AVERAGES	0.764	0.498	0.619	0.147	0.735	0.503	0.361

Table 6 shows the summary of the ranking of the renewable energy sources according to efficiency scores, using benchmark ranking, virtual efficiency, and cross efficiency approach. In this comparison, we exclude super efficiency approach, because we cannot get efficiency scores of the inefficient power plants. Therefore final ranking is obtained by the cumulative scores of each power plants for these three approaches. Therefore overall ranking of the renewable energy sources should be as follow: (1) geothermal, (2) wind-onshore, (3) solar PV, (4) wind-offshore (5), biomass, (6) hydropower, and (7) solar thermal plant.

Table 6: Results of Comparing Ranking of the Renewable Energy Sources					
Power Plants	Benchmarking Approach	Virtual Efficiency	Cross Efficiency	Cumulative Scores	Overall Ranking
Wind-onshore	2	2	1	5	2
Wind-offshore	2	6	5	13	4
Solar PV	2	3	3	8	3
Solar thermal	7	7	7	21	7
Geothermal	1	1	2	4	1
Biomass	5	5	4	14	5
Hydropower	6	4	6	16	6

SUMMARY AND CONCLUSION

In this paper, we want to determine the most efficient renewable energy source(s), with pre-determined input and output variables. We construct DEA framework to find efficiency scores of each power plant. We apply four different analytic approaches, benchmark ranking, cross-efficiency, super efficiency and virtual efficiency. We rank each power plant by using three of these approaches, and then we calculate the cumulative scores. Finally, we rank these power plants according to their cumulative scores. Figure 3 and Table 6 summarizes the contribution of each analytic technique to the cumulative scores of each plant.

As can be seen from Figure 3 and Table 6, geothermal is the most efficient renewable energy source, even though the cumulative scores of wind-onshore and solar photovoltaics is very close to the leading source. Although both biomass and wind-offshore are also efficient energy sources, their cumulative scores are very low, concerning the top three renewable energy sources. Wind-offshore is a relatively new technology for U.S. so that the TSLC cost is very high and it is ranked (4). Although biomass had a high capacity factor and created more than 150,000 jobs in 2015, it is ranked (5) because it requires an enormous amount of land. This also shows us the land requirement is an essential input variable for this analysis. Hydropower is ranked (6) in our analysis because it requires large land and water consumption for its operation. Lastly, solar thermal is labeled as the least efficient renewable energy sources for each analytical approach that we covered in this study. This is due to its highest TSLC and lowest capacity factor value.

Solar PV is the fastest growing power-generation globally. Last year, the total installation increased by 20% concerning the previous year, and it created direct and indirect 2.8 million jobs. About ten years ago, the TSLC of Solar PV was almost 400 $/MW, and it was the most expensive energy source in the IPCC the Fourth Assessment Report (2007). However in the IPCC the Fifth Assessment Report (2014), it is about 66 $/MW. Technological advances and subsidies lead this cost reduction and make photovoltaic technology one of the most efficient renewable energy sources. In our analysis, solar thermal technology is the least efficient renewable energy source because of its highest TSLC value. However, in the future, the advancements in these technologies, may make them more preferable with the reduction of cost functions.

Renewable energy sources are our essential weapons to fight global warming and reduce GHG emissions all over the world. According to the EIA data, with the expansion of these renewable energy sources, GHG emissions started to decline in the United States in last five years. Therefore, policymakers should encourage and subsidize these technologies, especially the most efficient ones: geothermal, wind power and solar PV to prevent severe consequences of global warming and climate change.

The Emergence of Entrepreneurial Ecosystem: How Early-stage Startups Build Partnerships

Jinyoung Kim
Korea University Business School
Email: jinyoungkim@korea.ac.kr

ABSTRACT

How early-stage new ventures develop partnerships has remained underinvestigated mostly due to the difficulty of observing their dynamic development processes. In this study, I have observed eighteen startups in embryonic stage directly every day by working as an in-house mentor for six months. My longitudinal in vivo observations result in three distinctive types of partnerships among early-stage startups: transaction-, relationship-, and collaboration-based partnerships.

KEYWORDS: partnership, startup, network development

INTRODUCTION

Recently alliance networks of new ventures have attracted research interests significantly, such as what type of network they govern and how the governance structures work (Hoang & Antoncic, 2003). One area of research interest is the contents of alliance network: how and through which media actors in these networks gain access to other parties' resources and what type of resources they gain access to. Startups without much resource to leverage are particularly at needs of alliance networks to be able to access more resources. Prior studies have found that startups benefit from alliance networks in diverse ways, such as superior innovation performance (Baum, Calabrese, & Silverman, 2000), raising more venture capital investment (Baum & Silverman, 2004), or accelerated launching at the stock market (Chang, 2004). Yet early-stage startups usually lack legitimacy, or minimum level or track records, to appear viable and attract partner candidates due to their liability of newness (Stinchcombe, 1965). Therefore, early-stage startups, especially those in their embryonic stage, find themselves at disadvantage to find alliance partners.

How early-stage startups find and build partnerships has been underinvestigated mostly due to the difficulties of observing and investigating the contents directly. Moreover, prior studies in alliance and network research have mostly look at the static nature of alliance networks, whereas developing and maintaining alliance networks are dynamic processes by nature (Parkhe, Wasserman, & Ralston, 2006). Recently a few studies have responded to this criticism and adopted a longitudinal research design to investigate the prolonged impact of startups' partnerships (e.g., Milanov & Fernhaber, 2009). Still the process of partnership development by startups in an embryonic stage of ideation and incorporation has been underinvestigated. Therefore, in this study, I investigate early-stage startups by directly observing how they identify potential partners and build the partnerships to pursue various objectives.

LITERATURE REVIEW

Prior studies in alliance and network research have shown the beneficial influence of alliance networks, such as new venture performance (Baum et al., 2000), new product

development (Deeds & Hill, 1996), or absorptive capacity (George, Zahra, Wheatley, & Khan, 2001). More specifically for startups, those with more alliance networks are likely to take less time to file for initial public offerings (Chang, 2004), and raise more investment from venture capitalist (Baum & Silverman, 2004). In general, alliance networks are beneficial for firms to certain degrees. What has been far less investigated is how these alliance networks emerge in the first place among early-stage startups.

For early-stage startups, one of the biggest challenges is resource constraints. Without much resource to start from, early-stage startups' appeal as alliance partner candidates is lukewarm at best. Non-existent track records to prove their legitimacy hardly help these startups to find potential partners, either. Startups' liability of newness combined with limited resource availability aggravates startups' attempt to search for partnership candidates. Yet lack of alliance networks becomes even further liability for startups (Oliver, 2001). In this grim situation, how do startups search and identify potential partners, and subsequently develop future partnerships to pursue mutually beneficial goals?

In order to answer this research question, I have directly observed 37 early-stage startups during a six-month period by mentoring them every day as an in-house mentor at the Korean incubator for international startups. In the following sections, I describe the research context and the findings.

METHODS

In this study, I have adopted a longitudinal single case study methodology to investigate the process of partnership building by early-stage startups. Single case study method is considered to be particularly suitable for revelatory cases (Eisenhardt & Graebner, 2007; Yin, 1994). Since the current case of K-Global not only describes a unique phenomenon of a hybrid incubating program for international startups but also benefits from direct, *in vivo* observation in a continuously longitudinal way, revelatory longitudinal single case study is an appropriate methodology for this study.

Research Context: K-Global

I had worked for K-Global (pseudonym) in Seoul, South Korea, as an in-house mentor and lecturer for six months from November 1st, 2016 to April 30th, 2017. K-Global is a public incubator run by a private incubating company. Seoul Metropolitan City (SMC) came up with an idea of launching K-Global, the very first startup incubating center for international startups in South Korea. By international startups, SMC refer to a team of entrepreneurs whose nationalities include at least one foreign country. Since all South Korean government's grants for entrepreneurs had been only for Korean citizens before the launch of K-Global, SMC's first attempt to subsidize foreign entrepreneurs had attracted quite an interest from foreigners in South Korea who were considering starting their own businesses. SMC provided the budget to launch K-Global, and teamed up with one of top private incubating companies to plan, establish, and manage everyday operations of K-Global. As a result, K-Global's management direction was uniquely carved out by two competing perspectives of public and private sectors' managers.

The first batch of 37 resident startups was selected in August 2016, and officially enrolled themselves at K-Global in October same year. SMC provided each startup with KRW10,000,000 (USD10,000 approximately) The official six-month program started in November 2016, when I also joined K-Global as an in-house mentor. Thanks to my position, I was able to observe startup entrepreneurs' interactions with one another directly. Since all

resident startups were given an office space at K-Global, physical propinquity of all 37 resident startups gave me a unique opportunity to conduct *in vivo* observations. K-Global became a giant petri dish for me to observe how each startup entrepreneur interact and subsequently create various types of relationships with one another.

Data Collection

During the six-month period, I had mentored the resident startups at K-Global every weekday from 10am to 3pm. In addition to myself, K-Global hired two more mentors who would visit K-Global once a week to provide mentoring sessions for their designated mentees. I was the only in-house mentor who closely mentored my designated mentees, but also provided advice to all other resident startups when requested. My responsibility as an in-house mentor was largely set in three folds: (1) face-to-face mentoring sessions with anyone who needs advice; (2) weekly offline/online communications, or face-to-face mentoring sessions if needed, with my eleven designated mentees; and (3) regular lecture sessions for all resident startups at K-Global. Majority of my work fell into the first category: advising startups in an ad-hoc basis whenever they need my advice, which is completely pull-based. The second category of having offline/online communications or face-to-face mentoring sessions with my eleven mentees was more of a push-based approach: I initiate communications to check the current status of each mentee.

During these two categories of work, I not only advised and handled their requests, but also inquired their status in terms of interactions with other resident startups. For my inquiry, I adopted a semistructured interview technique to garner process information on how startup cofounders' interactions with those of other startups had evolved. Among 37 resident startups, I found 18 startups developing and managing partnerships during the six-month period of my residency. Table 1 lists Table 1 lists 18 resident startups and quick descriptions on their products or services. Following Bhave's (1994) process model of entrepreneurial venture creation, each startup's commercialization stage is categorized into three stages: opportunity stage, technology setup and organization creation stage, and exchange stage. All startup names are pseudonyms.

Table 1. List of 18 resident startups at K-Global

Startup	Product/service	Startup Stage
BebeCo	Ergonomically designed babycare products for infants	Technology setup and organization creation
BuddyCo	Real-time mobile application that connects foreign tourists and local tour guides	Technology setup and organization creation
CareerCo	Online and mobile application to create smarter resumes	Opportunity stage
CodeCo	Education kit for kids to learn both hardware and software programming	Technology setup and organization creation
ConciergeCo	Travel platform that provides highly customized tours	Exchange stage
CosCo	Curated Korean beauty products that targets European markets	Exchange stage
CultureCo	Contents platform of Korean entertainment	Exchange stage
DesignCo	Design platform that connects consumer firms and entry-level designers	Exchange stage
DeviceCo	Affordable yet high-quality 3D printer	Exchange stage

EdutainCo	Contents creator that targets Spanish consumers who want to learn Korean language and culture	Technology setup and organization creation
EventCo	Platform service for organizing events and booking tickets	Technology setup and organization creation
FitCo	Mobile application that provides customized fitness assistance	Opportunity stage
FunCo	Media contents creator that focuses on Korean culture	Exchange stage
GlobalCo	Overseas education platform for Korean students who want to study abroad	Technology setup and organization creation
IncaCo	Korean beauty products that targets Latin American markets	Exchange stage
MetroCo	Entertainment and political news contents of Korean market for foreign consumers	Exchange stage
StyleCo	Burlesque-inspired style items	Technology setup and organization creation
ToyCo	Social network service for toy collectors	Exchange stage

RESULT

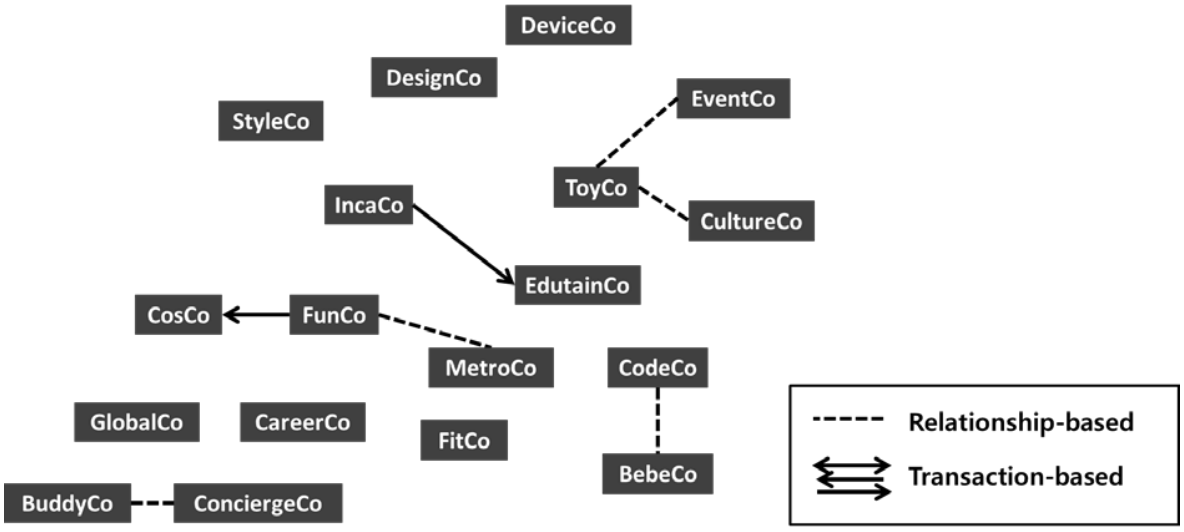
During the first two months, from November to December 2016, I had only witnessed casual and social interactions among resident startup entrepreneurs. Gradual clustering based on social relationships emerged during the first two months, largely based on two factors: (1) physical propinquity, such as sharing the same office, or close proximity of their offices, and (2) homophily in terms of their business ideas and nature of their businesses, such as targeting the same products or markets, and being technology-based or service-oriented startups. In this period, some entrepreneurs stood out as “social bees,” yet no distinctive patterns or concrete partnerships had emerged. Starting from January 2017, the third month of startups’ residency at K-Global, consistent patterns started to appear. These patterns show temporal clusters of three phases: (1) Phase 1 between early January and mid-February 2017, (2) Phase 2 between mid-February and early March 2017, and (3) Phase 3 between early March and late April 2017. I share my observation and analysis by following each phase in a chronological order.

During Phase 1, a few partnerships started to surface. Two distinctive patterns had emerged: (1) transaction-based partnerships started to happen among resident startups whose needs and solutions were matched, and (2) casual social relations started to be transformed into significantly strong relationship-based partnerships, such as dyadic relationships of informal mentor-mentee connections. The very first partnerships turned out to be mostly transaction-based partnerships, such as service contracts under which one startup provides its service to a fellow resident startup which happened to need that service. For instance, FunCo, a team of two media contents creators, which produces and distributes short video clips to introduce interesting aspects of Korean culture to English-speaking audience, had already equipped themselves with necessary capability to create media contents by themselves. On the other hand, CosCo, a team of a beauty specialist and a business person who curate Korean beauty products to cater to European consumers, was in need of an inexpensive media production service to create video clips for promotional purposes. Transactional partnership between FunCo and CosCo was sealed immediately, as CosCo’s demand- and FunCo’s supply-side factors were well aligned.

At the same time, unusually strong social relationships also sprang up. Unlike casual social relationships I have observed during the first two months, these strong ties were found to resemble a type of mentor-mentee bond. Majority of these strong relationships I had observed had happened between two startups which share a certain level of resemblance in terms of their target products or the type of industry where they were operating in. For instance, EdutainCo, a team of Spanish-speaking Korean students and Spanish nationals who develop an online platform for Spanish audience to learn Korean language and culture, started to seek advice from CultureCo, which had already launched an online platform to share media contents about Korean entertainment culture with wider audience in overseas countries. CultureCo was at the exchange stage: it already had secured the first batch of active online customers and had successfully organized entertainment events internationally. By constantly giving advice to EdutainCo, CultureCo unintentionally had assumed a role of informal, junior mentor of EdutainCo. This type of unusually strong relationship-based partnerships also happened between FunCo and MetroCo, both of which create media contents for English-speaking audience, and CodeCo and BebeCo, both of which develop working prototypes for their hardware products.

One interesting exception was ToyCo, a team of three engineers and a marketer which develops a social network service for toy collectors. Although ToyCo hardly shares any similarity in terms of target products or their nature of business, ToyCo had developed strong relationships with CultureCo and EventCo mostly by giving advices on entrepreneurial experiences in general, including its various experience in raising funds from both public and private sectors. Moreover, one of cofounders of ToyCo shared his own observations of other resident startups at K-Global with me, in such a way that he was proactively and intentionally looking for not only ToyCo's potential partners but also candidates for matchmaking. Figure 1 shows the partnerships developed during Phase 1.

Figure 1. Partnerships among startups in Phase 1

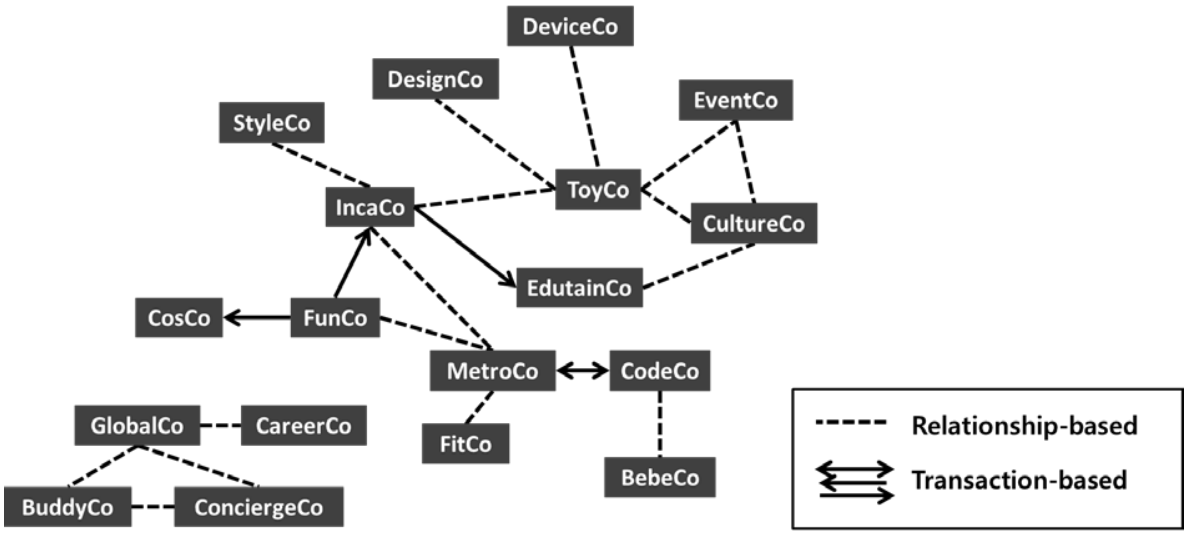


In sum, during the embryonic stage of creating a startup, entrepreneurs create primitive forms of alliance partnership based on a simple transaction-based partnership. Their rationale behind these decisions is more likely to use the very first partnership as a type of litmus test on how their partnerships would work out effectively. Therefore, I propose a following proposition based on my observation during Phase 1:

Proposition 1. Early-stage startup entrepreneurs are likely to engage themselves in simple transaction-based partnerships in order to coopt limited resources.

During Phase 2, more transaction- and relationship-based partnerships had sprung up, following the same patterns I had observed during Phase 1: (1) transaction-based partnerships, and (2) casual social relations transformed into significantly strong relationship-based partnerships. Figure 2 shows the partnerships developed in this period. As shown in Figure 2, startups develop mostly same types of partnerships. For instance, ToyCo and MetroCo were heavily involved in relationship-based partnerships with multiple startups, whereas FunCo was mostly developing transaction-based partnerships. One interesting exception was IncaCo, a husband and wife duo who try to establish Korean skincare service in Latin American countries. IncaCo developed both transaction- and relationship-based partnerships with almost equal dexterity. Moreover, I observed that IncaCo was an information conduit at K-Global. Not only IncaCo was an apt at scanning and searching for new information, it was also an effective information communicator for other resident startups at K-Global.

Figure 2. Partnerships among startups in Phase 2



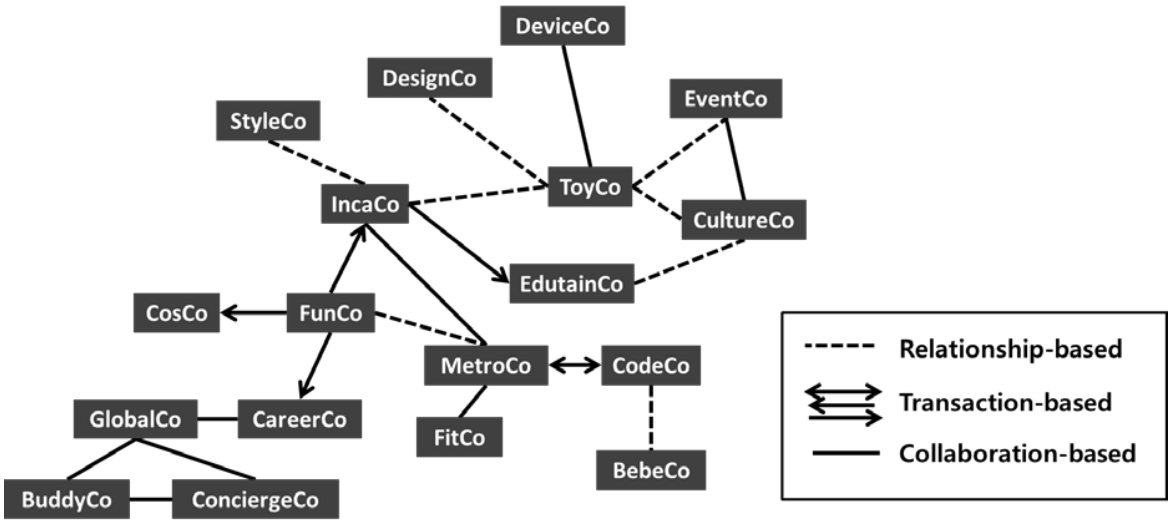
During Phase 3, the structure of partnerships among resident startups had rarely changed, except a new transaction-based relationship between FunCo and CareerCo. On the contrary, the nature of some partnerships show dramatic changes in this period. As shown in Figure 3, a group of relationship-based partnerships during Phase 2 had been transformed into collaboration-based partnerships, such as developing new business ideas together by pulling both parties' resources together. Eight relationship-based partnerships, which are DeviceCo-

ToyCo, EventCo-CultureCo, IncaCo-MetroCo, MetroCo-FitCo, GlobalCo-CareerCo, GlobalCo-BuddyCo, BuddyCo-ConciergeCo, and GlobalCo-ConciergeCo, had quickly been turned into collaboration-based partnerships to either develop new business ideas or expanding their product portfolio together for growth purposes. Interestingly, this transformation was never observed with transaction-based partnerships, which remained almost identical as a relationship between customer and service provider throughout Phase 2 and 3.

In comparison to startups which engage in transaction-based partnerships, those leveraging relationship-based partnerships are more likely to move forward to the next stage of collaboration-based partnerships. Therefore, I propose the following proposition based on my observation during Phase 2 and Phase 3:

Proposition 2. Early-stage startup entrepreneurs who start relationship-based partnerships with other entrepreneurs are likely to move forward their alliances into collaboration-based partnerships.

Figure 3. Partnerships among startups in Phase 3



DISCUSSION

In this study, I have observed early-stage startups directly during a six-month period, and identified three types of partnerships of early-stage startups: (1) transaction-based partnerships between startups one of which needs solutions and the other of which provides them, and (2) relationship-based partnerships between startups which build strong dyadic social relationships between advice-providers and advice-recipients, and (3) collaboration-based partnerships among startups which transform their relationship-based partnerships into more formal collaborations to develop future business ideas or expand the current businesses by pooling participating parties' resources together.

Transaction-based partnerships either happen at one point of time or continuously depending on the needs of startups which fall into the role of customers. Throughout the six-

month period of observation, the nature of transaction-based partnerships remains unchanged. In contrast, both relationship- and collaboration-based partnerships are observed to be strongly related, in such a way that relationship-based partnerships work as antecedents to pursue collaboration-based partnerships. Startups without much resources available or track records to prove their legitimacy have difficulties with defining assessment criteria to identify potential partners. By building relationship-based partnerships first, startups may be able to concretize assessment criteria heuristically. Positive experience of both parties that are engaged in relationship-based partnerships provide much needed assurance for both parties to pursue further partnerships which gradually turn into collaboration-based partnerships.

The findings of this study contributes to both academia and industry. By directly and longitudinally observing how early-stage startups develop partnerships in their embryonic stage, the dynamic process of partnership development is explained. Moreover, different types of partnerships are found to be leveraged in different ways to either solve problems efficiently or collaborate for new business opportunities. For practitioners, the findings of this study provide insights on how to develop incubating environments to enhance partnership developments among resident startups.

ABSTRACT

The job market has been experiencing a rapidly growing demand for business analytics professionals. In this fast-paced business world, current analytics programs need to follow the trends, tools, and concepts frequently used by industry to continuously improve their programs. Thus, this research-in-progress aims to identify the skills that industry is looking for in analytics professionals and determine the tools and concepts covered in the courses offered through analytics programs at numerous universities. The primary objective of this evolving study is to help the academic world to align their analytics curricula with business needs and expectations.

KEYWORDS: Analytics, Curriculum Design, Masters, and Job Market

INTRODUCTION

The number of job openings for business analytics positions (e.g., operations analytics, data scientist) is increasing at a remarkable pace. It is predicted that by 2020, the number of analytics jobs will increase by 28% and reach 2,720,000 (PWC, 2017). The salaries for business analytics jobs are also expected to go up. Nevertheless, the industry still faces difficulties in hiring analytics professionals; and the analytics job postings remain open for longer durations than other positions (Manyika et al., 2011; Columbus, 2017). The growth in demand for business analytics jobs has been the center of focus for several years in industry reports (Manyika et al., 2011; Columbus, 2017; PWC, 2017) and academic research (Chiang et al., 2012; Gorman & Klimberg, 2014; Mamonov et al., 2015; Rienzo & Chen, 2018). Hence, both industry and academia have placed efforts to train the future analytics workforce.

Universities, by designing business analytics (BA) programs, have been making a significant contribution to resolving this demand shortage. However, the major problem is the broad and often vague use of the business analytics job descriptions and the terms used, and the lack of definitions of the specific skills required by industry practitioners (Rienzo & Chen, 2018). Association to Advance Collegiate Schools of Business (AACSB) has been active in recent years to keep track and provide guidance for curriculum development for the discipline of Business Analytics. At a recent Summit organized by AACSB “to provide faculty participants

with a forum to learn about, share & discuss, and identify strategies & resources for Data/Business Analytics in the curriculum at their university" over 200 participants met from several different countries to discuss the scope of an effective BA/data analytics (DA) curriculum. Findings shared through best practices and lessons learned indicated very similar experiences of university programs: diversity of students' backgrounds and readiness, lack of clarity on industry needs, challenges of competent and experienced faculty, administrative challenges of developing interdisciplinary BA/DA programs, industry support for internships and capstone courses. With fast evolving technologies and vendor products the challenges of BA/DA curriculum get very difficult.

Many endeavors have strived to define the specific skills needed for business analytics graduates; however, most of these endeavors were restricted to data collected from a limited number of firm managers. We believe that, given the increasing demand for analytics professionals and ever-changing job descriptions, there still is a need to design a framework to help academia shape their business analytics curriculum in accordance with the industry needs. Hence, this paper proposes a novel framework based on a testbed consisting of tens of thousands of business analytics jobs analyzed to examine the fit against the curricula adopted by universities. In order to serve the industry practitioners and educators of business analytics, the primary objective of this study is to provide a framework that will help universities align their analytics curricula with industry needs and expectations. Specifically, this research-in-progress will focus on the following question: What are the computational tools, technical knowledge, and soft skills needed in the industry for business analytics graduates?

LITERATURE REVIEW

In our literature review, we first elaborate on the history of analytics and explain why the term "analytics" has become so popular in the last ten years. Then, we summarize publications regarding the development of analytics programs. The discussion in this literature review is particularly essential to readers to have a better understanding of the development process and the evolution of the analytics field in industry and how academia has been responding to this trend by initiating new programs.

Brief History of Analytics

The manufacturing industry, which was the backbone of the U.S economy during the late 20th century, widely used Operations Research (OR) for resource management and scheduling, and frequently employed descriptive and inferential statistics for quality and process management. Throughout the 1950s to 1970s, Business and Engineering schools developed new programs to satisfy the demand for newly emerging quantitative fields (e.g., Industrial Engineering, Management Science, and Operations Management). In the 1970s, although the computers were available before in the form of giant calculators, they were becoming commercially available. Thus, companies started using them for real-world purposes, such as storing and processing data. Universities witnessing the use cases of computers in the business world started offering programs in Information Technology (IT). Throughout the 1980s and 1990s, the collaboration among the three pillars of analytics, namely, statistics, optimization, and information technology remained negligible. Starting from the early 2000s, when companies realized that the use of technology in making business decisions was a differentiator and key to surviving in the market, they integrated statistical and optimization tools with computer systems under the umbrella of Business Intelligence (BI).

In today's world, with exponentially increasing computational power and data storage capabilities of computers, companies can store petabytes of information using distributed file systems (e.g., Hadoop). Big Data, as an emerging phenomenon, impacts numerous industries and how they conduct business. For instance, telecommunication companies use classification methods to predict which customers may churn; finance industry employs reinforcement learning to make stock buy/sell decisions; logistics firms determine the best route and inventory needs using real-time traffic data and optimization methods, etc. In the era of Big Data and Information Technology, Statistics, Operations Research, and Computer Science fields are more intertwined than ever before, and have merged as a new interdisciplinary field named "Business Analytics (BA)", "Data Analytics (DA)", or "Data Science". Therefore, academia is responding to this new and developing field by designing programs that will educate the next generation of analytics professionals.

Past Research Exploring Analytics Curriculum

In our literature review, we have examined several articles regarding the best practices to design and improve a business analytics curriculum. Table 1 summarizes the list of nine identified journal articles written between 2012 and 2018. Since many educators argue that math and programming are the pillars of data analysis, Aasheim et al. (2015) have investigated the requirements of analytics programs and found that existing business analytics curricula don't require general math or programming courses. Their study also states that business analytics programs lack emphasis on data capture and ethics.

Table 1: Summary of Literature Review

Article	Outlet	Scope	Methodology
Aasheim et al. 2015	Journal of Information Systems Education	Compare data science and BA programs	Analysis of 13 universities curricula and course descriptions
Cegielski & Jones-Farmer 2016	DS Journal of Innovative Education	Skills for entry-level BA jobs	Expert Panel (27 participants), Content Analysis (186 job postings), Survey (160 participants)
Chiang et al. 2012	ACM Transactions on MIS	IS discipline & programs challenges and opportunities	Discussed examples of curriculum design in universities
Gorman & Klimberg 2014	Interfaces	Comparison of different undergraduate and graduate BA programs	Examined 32 programs and interviewed 17 program representatives.
Mamonov et al. 2015	IS Education Journal	Discussing the design of BA curricula	Analyzed 8 BA job announcements and 6 BA programs
Rienzo & Chen 2018	DS Journal of Innovative Education	Apply Disruption Theory to guide design of BA curricula	Analyzed 70 BA programs and 400 indeed job announcement.

Tang & Sae-Lim 2016	Education for Information	Comparison of programs across disciplines: description, curriculum, focus, and courses.	Content analysis on 30 data science programs from 8 disciplines.
Wilder & Ozgur 2015	Informs Transactions on Education	Undergraduate curriculum design	Reviewed 5 curricula and 8 publications/ industry reports
Wixom et al. 2014	Communications of AIS	Assess the response to industry demand to BA and big data	Analyzed "BI Congress" events: Survey of 319 prof/614 students/446 practitioners.

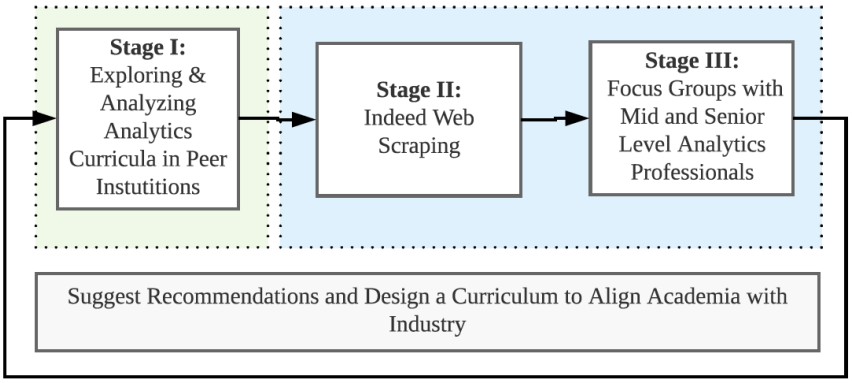
Cagielski and Jones-Farmer (2016), as well as Chiang et al. (2012), have discussed the development stages of business analytics curriculum and identified critical skills, tools, and languages. Their study reveals that technical skills in SAS, SQL, and Excel are essential for entry-level jobs. A survey conducted by Wixom et al. (2014) finds that industry is not satisfied with graduates' practical experience because academia does not focus on real-world application of analytics using real datasets, and many programs do not require internships to graduate. Gorman and Klimberg (2014) have conducted a comparative analysis using thirty-two programs to identify the differences among them. Their research indicates that there are significant differences in business analytics definition and directions of the programs. In a similar comparison analysis, after analyzing job announcements and business analytics curricula, Mamonov et al. (2015) also conclude that there is variance between programs regarding length, flexibility, tools, and methods. A study done by Tang and Sae-Lim (2016) reveals that there are significant differences across disciplines in curriculum requirements, domain knowledge or analytical focus, and courses. Wilder and Ozgur (2015) propose seven major courses and implementation guidelines. After analyzing seventy programs and four hundred job announcements, Rienzo and Chen (2018) recommend flexible, adaptable, and dynamic curricula.

FRAMEWORK & ANALYSIS

Our methodology to propose a business analytics curriculum that can satisfy industry's needs and expectations includes three stages:

- Stage 1: Peer university analysis: collecting and analyzing data regarding the current state: Analyzing universities that offer Master of Science in Business Analytics Programs- MSBA.
- Stage 2: Indeed.com web scraping: identifying industry's needs and expectations from analytics specialists using web scraping of thousands of job posts.
- Stage 3: Focus groups: Determining the needs and expectations of managers from entry-level analytics practitioners using focus groups

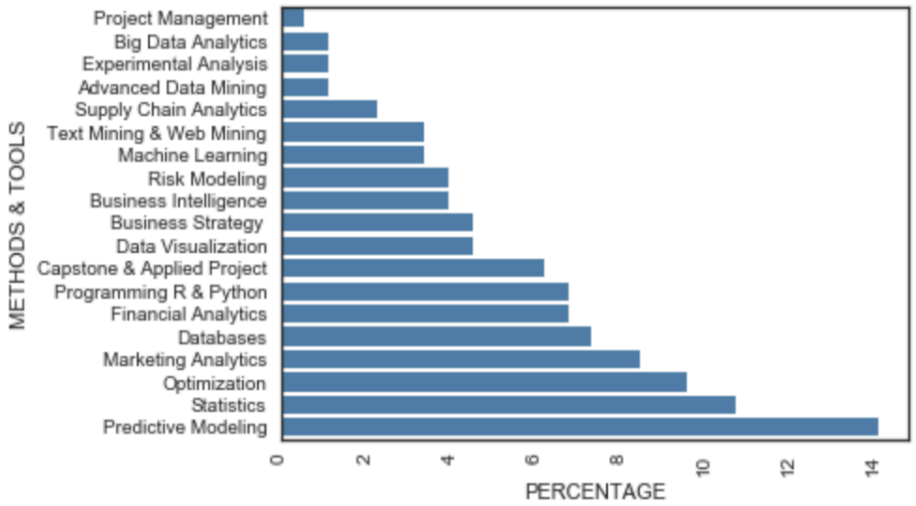
Figure 1: Proposed research framework



Peer University Analysis

In the peer university analysis stage, we have explored the curricula of Business Analytics programs in the Northeast Region of the US. To collect data, we have utilized the list of graduate business analytics programs maintained by the Institute for Advanced Analytics; then, we have narrowed down the list by filtering the location by state. We have reviewed the websites of the universities to collect the necessary data regarding the structure of the program and the list of courses. Our final list consists of 15 programs with a full Master's program in Business Analytics. We have coded each course in each program using the categories listed in Figure 2 and computed the percentage of courses in each category relative to the total number of courses required in the business analytics curricula across the different universities.

Figure 2: Percentage of course categories



The results of the peer university analysis show that programs in our sample have a focus on the basic analytics skills (e.g., predictive modeling) and the application of the skills in the financial and marketing sectors. However, the results show that less focus is on the managerial and organizational aspects such as project management which was highlighted as an important skill by prior research (Rienzo & Chen, 2018). Furthermore, big data concepts and programming

tools such as R and Python have less emphasis in our sample. We also think that cloud computing and the Hadoop ecosystem has not made into the curricula of these programs. Additionally, one of the most important pillars of business analytics that deals with design and analysis of experiments (e.g. A/B design for marketing) is not taught in the current analytics curricula of peer institutions.

WORK IN PROGRESS

Stage 2 and Stage 3 are still work-in-progress. In the following, we present a summary of the steps that we propose to implement.

Stage 2: *"indeed.com"* Job Scraping

In the second stage, we plan to employ a web scraping script in Python to collect job posting data (e.g., job name, description, and salary) from indeed.com. Our developed script automatically searches the website for user-defined job titles in given locations. We will conduct a job search for the postings that include the following keywords: *business analytics, data analytics, data analysis, data scientist, and analytics*. We will limit our search to the Northeast Region in the US following our analysis in stage 1. Specifically, we will focus our analysis on the following key areas:

- *What is the Importance of Advanced Degrees in Industry?*
- *What are the Concepts and Methods Required by Employers?*
- *What are the Tools needed?*
- *What is the Importance of Big Data in Analytics Curriculum?*

Stage 3: Focus Groups

In this section of our analysis, we will organize focus groups with mid-level and senior level analytics practitioners working in prominent companies in the US. Specifically, we will ask them the following questions and summarize their responses.

1. What are the tools you expect from entry level analytics specialist to know?
2. What are the concepts and methods entry level analytics practitioners in your team should know? How important is prior work experience for entry level analytics jobs?

CONCLUSION

In this research-in-progress paper, a framework for identifying the skills that industry is looking for in analytics professionals has been presented. The framework consists of exploring and analyzing business analytics curricula in universities, web scraping of thousands of business analytics jobs, and conducting focus groups with mid and senior level analytics industry professionals. The results of the first stage in the framework show the common courses emphasized across universities, as well as highlight the topics that have less focus in existing curricula. Topics that need more emphasis include managerial and organizational aspects such as project management, big data concepts, cloud computing, and analytics programming tools. In addition, the steps that will be implemented in stage 2 and stage 3 were discussed.

The Impact of Green Supply Chain Integration on the Triple Bottom Line

Zhaojun Han
Dalian University of Technology
Email: zhaojunhan@dlut.edu.cn

ABSTRACT

This study establishes a comprehensive framework of green supply chain integration (GSCI) based on the supply chain integration (SCI) literature and the natural-resource-based view (NRBV) and investigates the effects of different dimensions of GSCI on environmental, social, and economic performance. Model was tested based on data collected from 206 manufacturers.

KEYWORDS: Green supply chain management, Supply chain integration, Triple bottom line

INTRODUCTION

Green supply chain management (GSCM), which integrates environmental concerns into supply chain management (Srivastava, 2007), has emerged as an important strategy for companies to respond to the growing public environmental awareness and the rising government regulations (Rauer & Kaufmann, 2015; Vanpoucke et al., 2016). However, in practice, except for addressing environmental issues, companies continue to struggle with benefiting from GSCM (Wong et al., 2018). The main reason may be that supply chain managers have limited knowledge about how to effectively implement GSCM. This necessitates the research focus on “how to be green”, in addition to the traditional focus on “does it pay to be green”.

The majority of previous studies exploring GSCM practices have adopted a functional approach to GSCM and focused on specific functional areas (e.g., Kirchoff et al., 2016; Geng et al., 2017; Vanalle et al., 2017), such as green purchasing. This approach does extend environmental initiatives across supply chains. However, it fails to enable the concerted efforts of supply chain partners and does not exert the synergistic effect of supply chains. Since GSCM faces multiple complexities and uncertainties (Zhu et al., 2012) and involves a tremendous amount of investments and resources exchanges (Chen & Hung, 2014), an integrated approach to GSCM is much needed for companies to green their supply chains and reap performance benefits (Vachon & Klassen, 2008; Zhu et al., 2012; Yu et al., 2014).

Even though some recent studies have identified the importance of the integrated approach to GSCM and have coined the term green supply chain integration (GSCI) (Wu, 2013; Wong et al., 2015; Song et al., 2017), the conceptualization of GSCI is still ambiguous and fragmented. Some research highlights the integration of practices, such as integrating environmental management practices into supply chains (Wong et al., 2015), while others emphasizes the integration of participants, such as integration with suppliers and customers when managing environmental issues (Wu, 2013; Yu et al., 2014). In addition, the integration activities covered by existing literature are far from comprehensive and complete, making it difficult to distinguish the integrated approach from the collaborative approach. Overall, these mixed conceptualizations and operationalization of GSCI studies fail to capture the nature of supply chain integration (SCI).

In addition, our knowledge about how GSCI influences performance is still very limited and incomplete. To the best of our knowledge, there are no studies that have investigated the effect of GSCI on the triple bottom line (TBL) which includes economic, environmental, and social performance (Elkington, 1998). Furthermore, despite numerous studies on the link between GSCM and performance, social performance has received limited scholarly attention (De Giovanni, 2012). Existing literature mainly focuses on the effect of GSCI on environmental performance (e.g., Wong et al., 2018), financial performance (e.g., Song et al., 2017), operational performance (e.g., Yu et al., 2014; Song et al., 2017), and innovation performance (e.g., Wu, 2013; Dai et al., 2015).

Overall, the purpose of our study is twofold: building a comprehensive framework of GSCI based on SCI, addressing "how to be green"; and building a link between GSCI and the TBL, addressing "does it pay to be green". Our study integrates and extends the literature on GSCM and SCI, and provides significant guidelines for supply chain managers to leverage SCI to green their supply chains and earn benefits.

THEORETICAL BACKGROUND AND HYPOTHESES DEVELOPMENT

The Impact of GII on GSI and GCI

Extant literature has delineated that internal environmental management is the first step to GSCM (e.g., De Giovanni & Vinzi, 2012; Green et al., 2012). It lays the foundation for effective green collaboration with external supply chain partners (Yang et al., 2013). We argue that this assertion still holds for GSCI and postulate that GII is positively related to GSI and GCI. First, internal green information sharing means that internal departments are able to track real-time green-related information about products from raw materials to end products. Once they detect any problems, they will have to share this information with suppliers in that suppliers provide raw materials and may be responsible for some problems. In addition, getting green-related data also enhances the level of communication with customers about customers' environmental requirements and how companies are conforming to these requirements (Zhao et al., 2011). Therefore, internal green information sharing facilitates green integration with suppliers and customers.

Second, internal green process coordination breaks down functional barriers (Flynn et al., 2010) and enable different departments to work together to ensure all the internal processes are green (Yang et al., 2013). It creates a learning atmosphere across functions, which is likely to be expanded across companies and motivates companies to learn from their supply chain partners. As a result, the level of information sharing and communication with suppliers and customers will be high and suppliers and customers are more likely to involve in all processes of companies' green efforts. Dai et al. (2015) reported that internal integration of green product development process is positively related to supplier and customer integration of green product development process. Therefore, we argue that, internal green process coordination is positively related to green integration with suppliers and customers.

Third, internal strategic alliance implies that all departments are aware of green objectives and strategies and are willing to be subordinate their functional objectives to companies' objectives (Zhao et al., 2011). To achieve these objectives, employees from purchasing and marketing departments have to communicate with suppliers and customers about the green objectives and gain their support. From this perspective, internal green strategic alliance will facilitate green information sharing with suppliers and customers. In addition, internal strategic alliance shows

company commitment to the environment. Under this circumstance, companies will do their best to involve their supply chain partners in the environmental management and collaborate with them at all levels. Therefore, internal strategic alliance will have a positive effect on GSI and GCI. De Giovanni (2012) and Yang et al. (2013) both found that internal environmental management facilitates external environmental management with suppliers and customers. Therefore, we propose:

H1a: GII is positively related to GSI.
H1b: GII is positively related to GCI.

The Impact of GSCI on the TBL

The Impact Of GSCI on Environmental Performance

A positive relationship between internal environmental management and environmental performance is increasingly evidenced in the literature (Yang et al., 2013; Geng et al., 2017). For example, Yang et al. (2013) found that in the container shipping context, internal green practices have a significant positive effect on green performance. Geng et al. (2017) conducted a meta-analysis on the relationship between GSCM practices and performance and found that intra-organizational management enhances environmental performance. We argue that GII, as a better strategy to internal environmental management, will significantly increase environmental performance. First, green information sharing enables employees to detect green-related information in a timely manner. Then companies can adopt pollution prevention mechanisms to limit their emission. Real-time information about energy consumption also forces companies to constantly seeking ways to reduce the energy consumption. Second, internal green process coordination enables employees from different functions to voice their opinions, which will generate more solutions to environmental issues and increase environmental performance. Third, internal strategic alliance across functions enables a concerted effort of all employees to achieve the green objective. Therefore, we propose:

H2a: GII is positively related to environmental performance.

Environmental management being extended to supply chains is because it is well acknowledged that external environmental collaboration with suppliers and customers could significantly help companies go green (Rao & Holt, 2005). Previous studies pointed out that supplier and customer environmental collaboration influence performance in different ways. The results of their impact on environmental performance are mixed. For example, Geng et al. (2017) found that supplier integration positively influences environmental performance, while the effect of customer collaboration is nonsignificant. On the contrary, Jabbour et al. (2017) reported that environmental collaboration with customers is more effective for Brazilian companies to achieve environmental performance. In addition, Vachon and Klassen (2007) claimed that supplier collaboration is more effective at pollution prevention, while customer collaboration is more effective at pollution control. In this study, we argue that both GSI and GCI are positively related to environmental performance. First, green information sharing with suppliers clearly communicates environmental requirements to suppliers and enables companies to supervise whether suppliers are conforming to these requirements, forcing suppliers to follow the standards and provide green raw materials. In this regard, environmental performance can be ensured at the source of supply chains. Second, green process coordination with suppliers and customers involve them in all the processes of the value chain. This integration will help companies advance their environmental management technologies and improve their

environmental management capabilities (Geffen & Rothenberg, 2000), leading to better environmental performance. Third, green strategic alliance with suppliers and customers indicates that suppliers and customers have a clear understanding of companies' green objectives and strategies. In this case, suppliers are more likely to provide raw materials that are more environment-friendly and customers are more likely to ask for green packaging. Therefore, we propose:

H2b: GSI is positively related to environmental performance.
H2c: GCI is positively related to environmental performance.

The Impact of GSCI on Social Performance

Social performance has not received much scholarly attention in the literature on GSCM (De Giovanni, 2012). Only several studies have investigated the effect of GSCM on social performance. De Giovanni (2012) and Geng et al. (2017) both found that internal environmental management has a positive relationship with social performance. We argue that this relationship still holds for GII. First, internal green information sharing enables all employees from different departments to have access to green-related information. Some of this information may be related to workplace safety and employee health. Having this information, employees are able to take actions to protect themselves. As a result, the workplace safety of employees is likely to be enhanced. Second, internal process coordination enables a concerted effort of different functions in such processes as product design, increasing the likelihood that companies provide more environmental-friendly products into the markets. These environmental-friendly products may be able to improve the environmental safety of the community. Third, internal green strategic alliance reflects a company's determination to go green, which might be perceived by people from the community. This perception may increase their awareness of protecting environment and society. Therefore, we propose:

H3a: GII is positively related to social performance.

Though previous studies did not reported a positive relationship between external environmental collaboration and social performance (De Giovanni, 2012; Geng et al., 2017), we argue that green integration with suppliers and customers is able to increase social performance. This is because green integration with supply chain partners is different from the previous approach of environmental collaboration. On the one hand, it highlights a more close and integrated relationship, which may produce a wide range of performance. On the other hand, our approach of green integration includes all three strategies of NRBV, which may generate more competitive advantages. Specifically, green information sharing with suppliers and customers enables companies to get more information about the needs and requirements of stakeholders. It provides the opportunity for companies to address these needs and improve the well-being of stakeholders. In addition, green process coordination enables customers to solve environmental problems together with suppliers and customers. This significantly improves their problem-solving capabilities and efficiencies (Dai et al., 2017). As a result, serious pollutions may be solved immediately, reducing their potential damage to stakeholders. Green strategic alliance with suppliers and customers improves their commitment to environment. Suppliers may provide more environmental-friendly raw materials and customers may require more environmental-friendly products. This may require companies to build more environmental-friendly production lines, which will directly improve employees' working conditions and ensure their health and safety. Therefore, we propose:

H3b: GSI is positively related to social performance.
H3c: GCI is positively related to social performance.

The Impact of GSCI on Economic Performance

A lot of scholars have claimed that economic benefits are the major driver for companies to green their supply chains (e.g., Bowen et al., 2002; Kirchoff et al., 2016). Despite the numerous studies, the findings of whether GSCM improves economic performance are still mixed (Golicic & Smith, 2013; Geng et al., 2017). For example, Zhu and Sarkis (2004) and Zhu et al. (2005) argued that for Chinese manufacturers, GSCM practices are unable to create better economic performance. On the contrary, recent studies mainly reported a positive relationship between GSCM and economic performance (e.g., Geng et al., 2017; Schmidt et al., 2017). For example, Geng et al. (2017) found that internal environmental management, green collaboration with suppliers and customers all lead to a better economic performance. In line with this study, we argue that each dimension of GSCI has the possibility to increase economic performance. GII increases economic performance in three ways. First, internal green information sharing facilitates communication among different functions, reducing the cost of communication. Second, internal process coordination establishes a coordinated mechanism for different functions to work together, reducing the cost of coordination and conflict revolution. Third, internal strategic alliance is a signal to customers that this company commits to environment, which may increase product sales. Therefore, we propose:

H4a: GII is positively related to economic performance.

Li et al. (2016) found that green supply chain processes play an important role in improving financial performance. Yang et al. (2013) also reported that external collaboration with supply chain partners influence firm competitiveness positively. Similarly, we argue that GSI and GCI may be able to improve economic performance. First, green information sharing with supply chain partners enables companies to have real-time information about how suppliers are operating, reducing supervision cost. Second, green process coordination with supply chain partners promotes joint problem-solving which may generates more economical solutions. It also encourages supply chain partners to share the risks and costs when solving environmental problems, leading to better economic performance. Third, green strategic alliance with suppliers and customers indicates that companies view environment as a strategic objective, which may help companies build a good reputation and attract more customers. As a result, sales will be improved. In addition, to be green also implies to reduce waste. Therefore, the implementation of GSCI will inevitably save cost for companies. Therefore, we propose:

H4b: GSI is positively related to economic performance.
H4c: GCI is positively related to economic performance.

METHODOLOGY

Sampling and Data Collection

We collected data from manufacturing companies located in four representative regions in China (i.e. Bohai Bay Economic Rim, Pearl River Delta, Yangzi River Delta, and other areas in China) for its large size with uneven economic development (Chan et al., 2016). Specifically, other areas include northeastern, central, and western parts of China, which represent a relatively lower stage of economic development compared with coastal areas. We randomly

selected sampling companies from the directory provided by National Bureau of Statistic of China, covering diverse industries including automobiles, electronics, computers, food, chemicals, and so on. Phone contacts were made before mailing the questionnaire so that the key informant who was knowledgeable about supply chain management could be identified and ensured his/her agreement to participate in the survey.

Table 1: Profiles of Responding Companies			
INDUSTRY	PERCENTAGE	REGION	PERCENTAGE
Metal, Mechanical & Engineering	42.7%	Bohai Bay Economic Rim	32.2%
Electronics & Electrical	18.7	Yangzi River Delta	24.6
Textiles & Apparel	11.7	Pearl River Delta	21.6
Chemicals & Petrochemicals	8.2	Other areas in China	21.6
Building Materials	4.7		
Publishing and Printing	5.3		
Rubber & Plastics	3.5		
Food, Beverage, Alcohol & Cigarettes	3.5		
Pharmaceutical & Medicals	1.8		

A questionnaire with a cover letter highlighting the objectives of this survey and some guidelines on how to answer it was emailed to informants. Follow-up phone calls and reminding emails were made to improve response rate (Chen et al., 2016). We contacted 2710 companies in total, and distributed questionnaires to 696 companies that agreed to participate in the survey. 206 usable samples were finally returned, reflecting a response rate of 24.6 percent. Table 1 shows the profile of the samples. Table 2 shows the information of the respondents. Most of them were middle or top managers and had been in their positions for six or more years, suggesting that they were knowledgeable about GSCM practices of their company.

Table 2: Respondent Characteristics	
TENURE OF CURRENT POSITION IN FIRM (YEARS)	PERCENTAGE
≤1	4.1%
2–5	22.8
6–10	39.8
11–15	18.7
≥16	14.6
POSITION OF RESPONDENT	PERCENTAGE
Top manager	20.5%
Middle manager	74.9
Others (e.g. purchaser and salesman)	4.7

Measures

We developed the measures based on previous literature, as well as the interviews with managers. First, we developed an English version of the questionnaire based on a thorough review of relevant literature. Second, we translated initial questionnaire into Chinese, and then back-translated by two professionals to ensure the conceptual equivalence. Finally, we refined

the measures based on the in-depth interviews with managers from 18 companies during the pilot test stage. We modified the wording of some items to ensure all items were understandable and relevant to GSCM practices in China. The constructs were all measured on a seven-point Likert scale.

The measures for green information sharing, green process coordination, and green strategic alliance were adapted from Vachon and Klassen (2006), Flynn et al. (2010), and Wong et al. (2015). Respondents were asked to rate the extent their companies implement these practices, with "1" indicating the practices were not at all implemented and "7" indicating they were extensively implemented. The measures for economic performance were adopted from Dong et al. (2016) and the measures for environmental performance were adopted from Flynn et al. (2010). The respondents rated the performance measures compared with their major competitors, with "1" meaning "much worse" and "7" meaning "much better".

Non-response Bias and Common Method Bias

Following the procedure suggested by Armstrong and Overton (1977), we compared the demographic variables and key constructs of the first and last quartile of responses. This comparison revealed no significant differences between the two quartiles. We also made random follow-up calls to 30 firms that declined to participate in the survey to identify the reasons for their non-participation. These reasons included lack of time, lack of resources, and no interest. None of these reasons alluded to the possibility of systematic bias. Thus, non-response bias was not a big concern in this study.

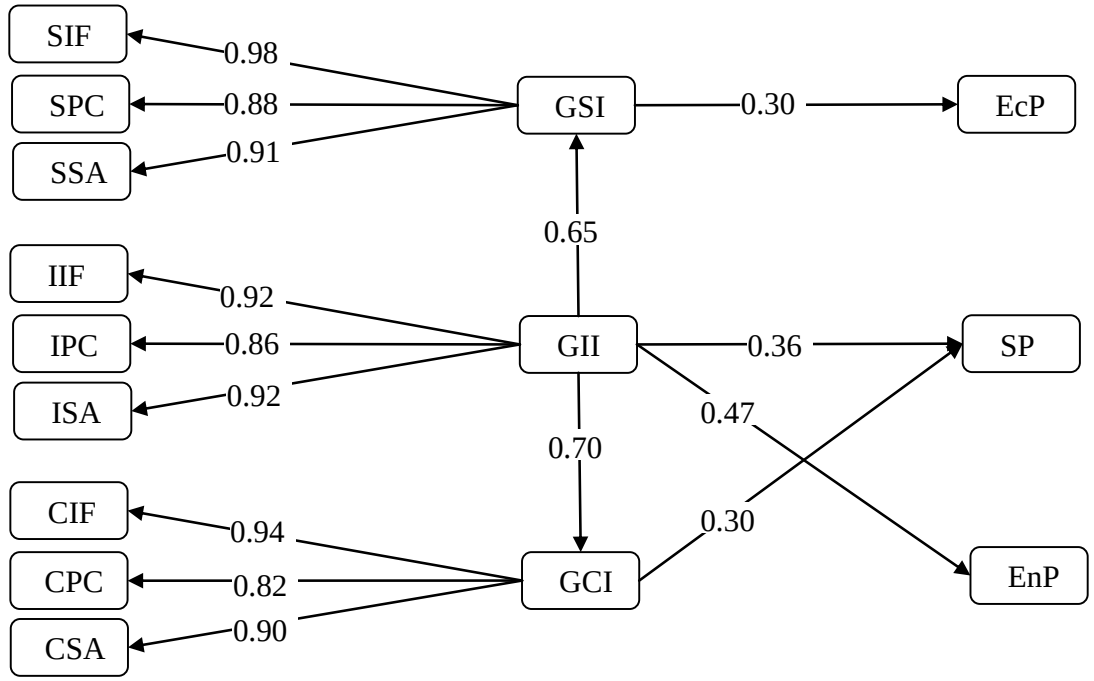
Because we only had one respondent for each questionnaire, common method bias might be a problem. We undertook several procedures to reduce the potential common method bias. First, in the questionnaire design stage, we appropriately arranged the order of questionnaire items, keeping adjacent variables in the conceptual model far away, to reduce the respondent's consistent tendency. This decreases common method bias to a certain degree (Podsakoff & Organ, 1986; Podsakoff et al., 2003). Second, we made sure we only targeted respondents that were very familiar with the content of our constructs. The accurate understanding of the items would decrease respondents' consistent possibility. After data collection, Harman's single-factor test was performed using exploratory factor analysis (EFA) (Podsakoff & Organ, 1986; Podsakoff et al., 2003). The results showed eight distinct factors with eigenvalues above 1.0, explaining 74.40% of the total variance. The first factor explained 42.71% of the variance, which are not the majority of the total variance.

Construct Validity

Confirmatory factor analysis (CFA) was conducted to assess convergent and divergent validity. To assess convergent validity, a CFA model was tested in which each item was linked to its corresponding construct, and the covariances among constructs were freely estimated. The model fit indices were χ^2=2475.84 with d.f.=1473, RMSEA=0.057, NNFI=0.98, CFI=0.98, Standardized RMR=0.044, indicating that the model was acceptable (Hu & Bentler, 1999). Furthermore, all factor loadings were greater than 0.50 and all t-values were greater than 2.0, ensuring convergent validity (Fornell & Larcker, 1981). To assess discriminant validity, we built a constrained CFA model in which the correlation between each possible pair of constructs was fixed to 1.0. This model was compared with the original unconstrained model, in which the correlations were freely estimated. All differences of χ2 were significant at the 0.01 significance level, indicating that discriminant validity was ensured (Fornell & Larcker, 1981). The

Cronbach's alpha values were all above 0.80. Thus, reliability of these constructs was ensured (Flynn et al., 1990)

Figure 1: SEM results



IF-information sharing; PC-process coordination; SA-strategic alliance; EcP-economic performance; SP-social performance; Enp-Environmental performance

Analyses and Results

In this study, we use structural equation modeling (SEM) to test our hypotheses. The results were run by LISREL 8.54 with the maximum likelihood estimation method. The goodness of fit indices of our model is acceptable (χ^2 (1519) = 2723.66, NNFI = 0.98, CFI = 0.98, RMSEA = 0.062, and SRMR = 0.10). Figure 1 shows the SEM results with standardized coefficients for the paths significant at the 0.05 level.

DISCUSSION

Consistent with the findings of previous studies, such as Wong et al. (2018) and De Giovanni (2012), our results find that GII is positively related to GSI and GCI. This indicates that GII lays the foundation for green integration with supply chain partners. On the one hand, GII shows a company's commitment to environment. This may get supply chain partners much more serious about going green, so that they will be more willing to involve in companies' green processes. On the other hand, green integration is a new approach to GSCM. It includes three important aspects. Companies may bring this knowledge to supply chain partners on how green integration should be conducted (Simpson et al., 2007).

Out of the three dimensions of GSCI, only GII is positively related to environmental performance, while GSI and GCI have no relationship with environmental performance. These findings are

consistent with those of Wong et al. (2018), which also adopted an integrated approach and only found a positive relationship between internal sustainable development and economic performance. However, in terms of green collaboration, both Tachizawa et al. (2015) and De Giovanni (2012) pointed out that green collaboration with supply chain partners has the ability to enhance environmental performance. These inconclusive results suggest that the integrated approach is different from the collaborative approach and that green integration with supply chain partners has not yet been able to improve environmental performance. In other words, the process of green integration with suppliers and customers is very complex and has been implemented at a very low level. It is difficult to influence environmental performance at the current level of green integration with supply chain partners.

In terms of social performance, our results find that GII and GCI are positively related to social performance, while GSI has no effect on social performance. These findings are partially supported by previous studies. For example, De Giovanni (2012) and Geng et al. (2017) both found that internal environmental management has a positive relationship with social performance, while external collaboration with supply chain partners is not significantly related to social performance. One possible explanation is that companies always want to attract customers with their green image (Lo, 2014). Under this circumstance, they will value customers' voice in the process of going green. As one important stakeholder to companies, customers may put themselves in the shoes of stakeholders and urge companies to address the well-being of all stakeholders. A close and integrated relationship with customers may also prompt customers to help companies improve the well-being of all stakeholders.

In terms of economic performance, we find that out of the three dimensions of GSCI, only GSI leads to a better economic performance, while GII and GCI are not related to economic performance. These results are in line with some of the previous literature. For example, Zhu and Sarkis (2007), Green et al. (2012), Golicic and Smith (2013), and Schmidt et al. (2017) all pointed out that working with suppliers on green practices is less costly than the other green practices and it is the best indicator of economic performance. The other green activities, such as GII and GCI may take more time to generate profitability (Golicic & Smith, 2013; Wong et al., 2018). Thus, our research reinforces the importance of GSI in proving economic performance.

CONCLUSIONS AND LIMITATIONS

Our study adopts a SCI approach to GSCM, builds a comprehensive framework of GSCI based on SCI and NRBV, and tests the effect of the three dimensions of GSCI on the TBL. Our results show that GII is positively related to GSI and GCI. GII has the broadest effect on performance, improving both environmental and social performance. GSI is the only dimension that improves economic performance and GCI is the only dimension that improves social performance.

Despite the significant theoretical and managerial contributions, this study still suffers from some limitations which may provide directions for future research. First, cross-sectional data were used to test the concept model in this study. This only provided a snapshot of the relationship between GSCI and the TBL. Future research should use the longitudinal data to examine the set of relationships. Second, we only focused on the performance of focal companies. This limits our understanding of the benefits of GSCI from the supply chain perspective. Future studies could consider collecting performance data from suppliers and customers. Third, we used one respondent to answer the entire questionnaire, which may lead

to common method bias. Though our test showed that common method bias was not a big concern in this study, future studies are recommended to avoid using one respondent.

ACKNOWLEDGEMENT

This study was supported by the Start-up Research Fund from Dalian University of Technology (No. 1201-852009).

ABSTRACT

Disruptive innovations such as wireless communications and disruptive business model innovations deployed by Airbnb and Uber have changed the value propositions and value creation of long established and emerging businesses. The primary objective of this research is to quantify the impact of key exogenous variables such as disruptive innovation on sustainable value creation of an entrepreneurial engagement in the renewable energy sector in developed economies. The outcome of this research has enhanced our knowledge base on how key antecedents disruptive innovation, and knowledge creation assist in creating verdant value propositions, delivery, and sustainable value in RE markets in developed economies.

KEYWORDS: Disruptive Innovation, Renewable Energy, Value Proposition, Sustainable Value, and Developed Economies

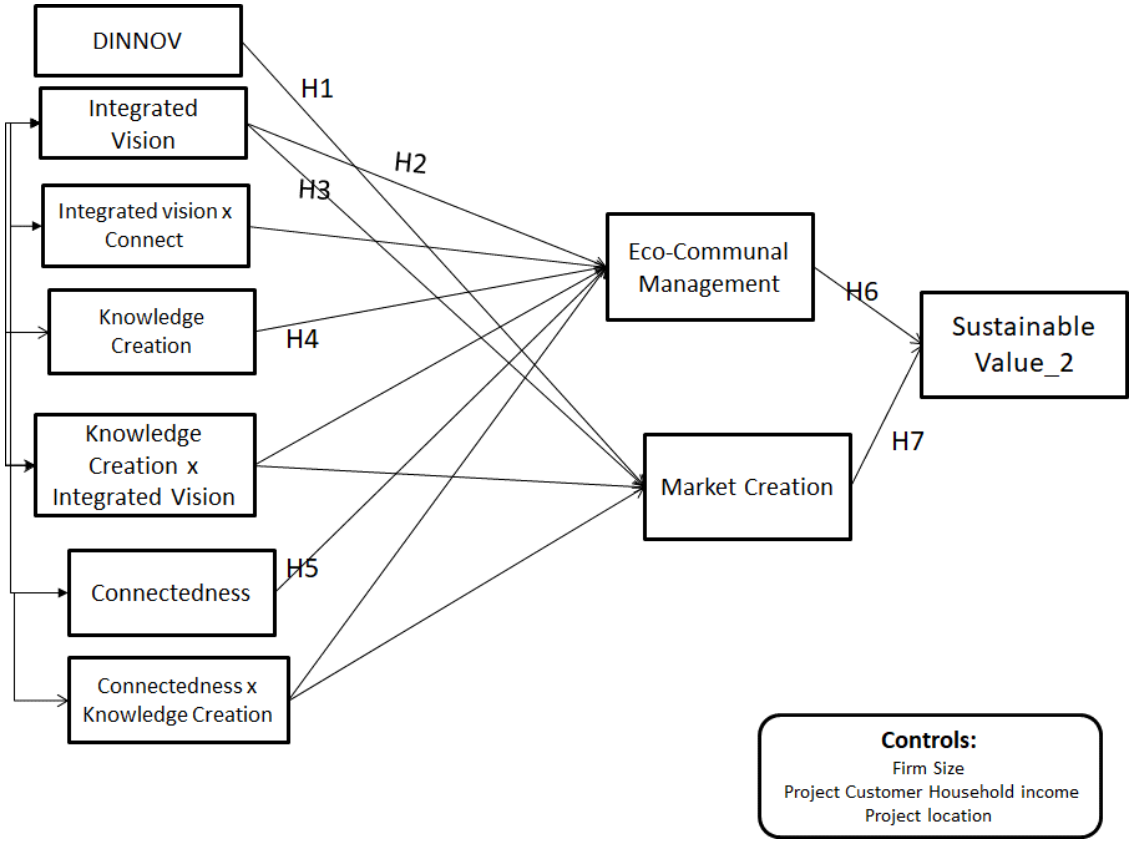
INTRODUCTION

Technological and business innovations play major roles in the functioning of developed economies. Technological developments are especially heavily utilized to optimize the cost of power generation from renewables, and have made considerable advances in achieving cost parity for wind power generation in recent years. Disruptive business models and technological revolutions have significant and substantial implications for the outcomes of renewable energy projects. Disruptive business model innovations reconfigure business opportunity recognition, value proposition and co-creation, and deliverables in the rapidly changing business and technology landscape of today (Hart & Christensen, 2002; Massa & Tucci, 2013). Multisided business models, in conjunction with multipurpose platforms and increasing web capabilities, are hastening changes in techno-economic paradigms (Bughin, Chui, & Manyika, 2010) and market orientations, resulting in significant implications for renewable energy businesses long-desired in developed economies (Viswanathan, Seth, Gau, & Chaturvedi, 2009).

Moreover, disruptive innovations attenuate the impacts of environmental selection on the genesis and diffusion of inventions enabled by the workings of embedded institutional and market structures (Luhmann, 1995; Nelson & Winter, 1977; Smits, Kuhlmann, & Shapira, 2010). In the context of developed economies, sustained innovation plays a more prevalent role than disruptive modernization. However, we predict that a disruptive revolution that includes both technology and business model innovations will play an appreciable role in changing socio-technical paradigms and have important implications for the outcomes of RE businesses (Boons et al., 2013; Hall et al., 2010).

Based on this framework, we have developed a model and associated hypotheses, as shown in Figure 1.

Figure 1. Hypothesized Model for Determining the Implications of Disruptive Innovations for the the Outcomes of RE Businesses in Developed Economies



HYPOTHESES

Disruptive Innovation (DINNOV)

Disruptive innovations that include technological and business model inventions have significant and substantial implications for the outcomes of renewable energy businesses. Disruptive innovations reconfigure business opportunity identification, value proposition and creation, and deliverables in this rapidly changing business and technology landscape (Christensen, Horn, & Johnson, 2008; Hart & Christensen, 2002; Massa & Tucci, 2013). Emerging multisided business models, in conjunction with multipurpose platforms in the 4th Industrial Revolution (where integrated cyber-physical-biological systems are hastened by additive manufacturing, AI, autonomous systems, advanced robotics, and decision support systems) are changing fundamental buyer-seller relationships and hastening socio-technological paradigm shifts (Bughin, Chui, & Manyika, 2010; Elfring & Hulsink, 2003). Such transitions are altering market orientations and have significant implications for renewable energy businesses in developed economies (Viswanathan, Seth, Gau, & Chaturvedi, 2009). Based on these recent changes, we hypothesize that disruptive innovation will have a positive and direct impact on market creation.

Hypothesis 1. Disruptive innovation is positively related to market creation, after controlling for firm size, project customer household income, and project location.

Integrated Vision

Integrated vision, which sets the overarching business strategy and rationale of a firm as an engagement with entrepreneurial action, has a significant and substantial impact on the formulation of management and market strategies of business interest (Ireland et al., 2009; Elfring & Hulsink, 2003). A clear and well-articulated strategic vision enables the establishment of capable management techniques that allow RE businesses to differentiate themselves from competitors; this is accomplished by creating aggregated value chains that optimize economic, social, and ecological benefits. In the context of developed economies, the formulation and deployment of such integrated strategic visions are imperative for successful renewable energy businesses hoping to create sustainable value. This is due to the highly competitive market structure supported by an established regulatory framework and significant sunk capital in conventional energy generation and distribution systems (Schoemaker, 1992).

Based on this rationale, we believe that integrated vision will be positively related to eco-communal management, after controlling for firm size, project customer household income, reflective practices, and project location, as stated in Hypothesis 2.

> *Hypothesis 2. Integrated vision is positively related to eco-communal management, after controlling for firm size, project customer household income, and project location.*

Integrated vision defines the perimeters of the markets served through entrepreneurial actions by providing creative solutions to challenging energy and related problems and demands. Based on these assertions, we hypothesize that integrated vision has a positive, significant, and substantial relationship with market creation, as stated in Hypothesis 3.

> *Hypothesis 3. Integrated vision is positively related to market creation, after controlling for firm size, project customer household income, and project location*.

Knowledge Creation

Knowledge creation refers to information formation related to customer needs, the project itself, related technologies and resources, and the overarching economic, ecological, and social issues accessed through socialization, externalization, internalization, and combined processes (Nonaka et al., 1994). In developed economies, knowledge creation plays a major role in the functioning of the economy and society at large. Based on these reasons, we hypothesize that knowledge creation (Dewey, 1929; Hessels & Van Lente, 2008) is positively related to eco-communal management, as presented in Hypothesis 4.

> *Hypothesis 4. Knowledge creation is positively related to eco-communal management, after controlling for firm size, project customer household income, and project/business location*.

Impact of Connectedness on Eco-communal Management

Connectedness, which involves the relational dynamics of the key decisionmaker of an RE business with stakeholders (including business staff, end users, the business/project host community, the ecosphere, and relevant investors and regulators) of a business or project, has a significant impact on the strategic management of that business. The relational spheres and embeddedness of the business establishes essential attributes of the business culture and impinges on its long-term and day-to-day operations (Dhanaraj, Lyles, Steensma, & Tihanyi, 2004). Based on these reasons, we predict that connectedness is positively related to eco-communal management, as stated in Hypothesis 5.

Hypothesis 5. Connectedness is positively related to eco-communal management, after controlling for firm size, project customer household income, and project location.

Impact of Eco-communal Management on Sustainable Value 2 (SV2)

Eco-communal management, which we have defined as the key management strategy of a renewable energy business (or project) that creates integrated economic, ecological, and social benefits for all stakeholders, is the primary pathway for translating the integrated vision, know-how, resources, and relational capabilities of the RE business into sustainable value (Schaltegger & Wagner, 2011). Sustainable value 2 (SV2) is a second-order factor with three first-order variables; it contains 12 items. Based on this premise, we reason that eco-communal management has a positive, significant, and substantial relationship with sustainable value.

Hypothesis 6. Eco-communal management is positively related to sustainable value 2 (SV2), after controlling for firm size, project customer household income, and project location.

Impact of Market Creation on Sustainable Value 2 (SV2)

Market creation, which is framed by the entrepreneurial drive of an RE business, is an essential part of product/service offerings, opportunity recognition, value proposition and delivery, and monetization; it has a significant impact on the sustainable value created by a businesses (Schaltegger & Wagner, 2011; Laszlo, 2008). Based on these assertions, we hypothesize that market creation is positively related to the desired outcomes integrated into an RE business or project (SV2).

Hypothesis 7. Market creation is positively related to sustainable value 2 (SV2), after controlling for firm size, project customer household income, and project location.

RESEARCH METHODS

Measures

All variables used in this research employed 5-point Likert scales.

Disruptive Innovation (DINNOV)

Disruptive innovation (α = .88) was measured using five items adapted from the works of Govindarajan and Kopalle (2006).

Integrated Vision (IVN)

We measured integrated vision with two first-order factors and a total of four items (α = .82) adapted from the works of Carroll et al. (2005).

Knowledge Creation (KC)

Knowledge creation was measured with four first-order factors and a total of 13 items (α = 0.94) adapted from Schulze and Hoegl (2006, 2008).

Connectedness (Connect)

We used two first-order factors and a total of six items (α = .93) from van Bel et al. (2009).

Eco-communal Management (EcoMng)

Eco-communal management is a management strategy for RE businesses that creates a symbiotic and synergistic partnership among profit-based, environmental, and societal goals (Hart & Dowell, 2010). It was measured using five items (α = .84).

Transition Engagement (TranEng)

Transition engagement refers to transformational changes brought about by RE development that is contextualized to local needs and capabilities and facilitates socio-technical paradigm shifts. It was measured with two items (α = .82) adapted from Bono and Anderson (2005) and Kayworth and Leidner (2002).

Market Creation (MKC)

Market creation was measured using five items (α = .78) adapted from the works of Jain and Kaur (2004).

Sustainable Value (SV2)

We used three first-order factors and a total of 12 items (α = .94) from Zhu et al. (2008) and meaningfulness items adapted from the works of May et al. (2004).

Controls

We utilized three controls in this research:

1. Firm size, which was expressed by the number of people the company employed. We used firm size as a control because of the thematic differences in entrepreneurial strategies that established and start-up renewable energy businesses tend to deploy (Hockerts & Wüstenhagen, 2010).
2. Project customer household income assesses the before tax income (in USD) of RE project customers (Whitmarsh & O'Neill, 2010). We utilized household income as a control because of its multilevel relationships with energy consumption, GDP growth, income generation, and environmental implications associated with increased energy consumption (Fang, 2011).
3. Project location was utilized to account for regional differences in the applications of renewable energy businesses and projects. These differences include market conditions, entrepreneurial climate, regulatory policies, financing instruments, and environmental selections, all of which impact RE business outcomes (Reiche & Bechberger, 2004).

Instrument Development and Testing

To ensure the reliability, validity, and appropriateness of the survey instrument, we conducted a pilot test administered to 40 key decision-makers engaged in renewable energy businesses in developed economies.

Data and Samples

Data were gathered from 222 key decision-makers in renewable energy businesses and projects, primarily in five developed economies (US, Canada, Germany, Japan, and the UK) but with a few responses from France and Norway. These key decision-makers were identified through the personal networks and business relationships of the researchers.

A total of 45.5% of the respondents were senior executives (CEO, COO, CFO, or CTO), and 54% were senior manager/managers with titles of project director or program manager.

Data Screening

We collected 222 complete survey responses that were free of missing data and contained data adequate for further analysis.

Analysis

As a part of our overall investigation, we conducted an exploratory factor analysis (EFA) and confirmatory factor analysis (CFA) with and without common latent factors, followed by structural equation modeling (SEM).

RESULTS

Exploratory Factor Analysis

We submitted the 47-item scale to an EFA. Several statistics indicated that the data were adequate and appropriate for further examination. These included a Kaiser-Meyer-Olkin (KMO) statistic of 0.921 and a significant Bartlett's test of sphericity ($\chi 2 = 21{,}708$, df = 5253, and $p < 0.000$) indicating sufficient inter-correlations. All commonalities were above 0.40, further confirming that each item shared some common variance with the other items (Hair et al., 2010).

Measurement Model

The confirmatory factors analysis of the measurement model yielded good model fit statistics with $\chi^2 = 1802.69$, degree of freedom (df) = 977, CFI = .900, and RMSEA = .062 (Hair et al., 2010), as shown in Table 1. Together, these indicate the validity of the factor structure.

Table 1. CFA Model Fit Statistics

	DE CFA SM_2
χ^2	1802.69
df	977
p	0.0000
CMIN/df	1.845
CFI	0.900
TLI	0.889
RMSEA	0.062
SRMR	0.09
PCLOSE	0.00

The CFA value met all validity and reliability requirements, indicating that the model fit the data well. The composite reliability for all of the constructs was greater than 0.7, and the average variance extracted (AVE) met the requirement for convergent validity. The maximum shared variances (MSV) and average shared variances (ASV) were less than the AVE, meeting the discriminate validity requirements (Fornell & Larcker, 1981). The reliability requirements were met with both the Cronbach's alpha and composite reliability for each construct greater than 0.7.

The effects of common method bias were checked by comparing the CFA results with and without common latent factors (CLFs), following Gaskin's (2012) recommendations. Also, there was no difference between the CFA results with and without CLFs, indicating that common method bias did not have a significant and substantial effect on the data collected.

Structural Equation Modeling (SEM) Results

The hypothesized model tested as shown in Figure 2 fit the data well, with model fit statistics of: $\chi^2 = 19.08$, df = 11, CMIN/df = 1.73, CFI = .998, and $p > .05$ (Hu & Bentler, 1999; Tabachnick & Fidell, 2007). A summary of the key model fit statistics can be found in Table 2.

Table 2. SEM Key Model Fit Statistics

	SEM Model SM_2_V3 + DiNNOV
χ^2	19.08
df	11
p	0.0597
CMIN/df	1.734
CFI	0.998
TLI	0.982
RMSEA	0.058
SRMR	0.014
PCLOSE	0.342

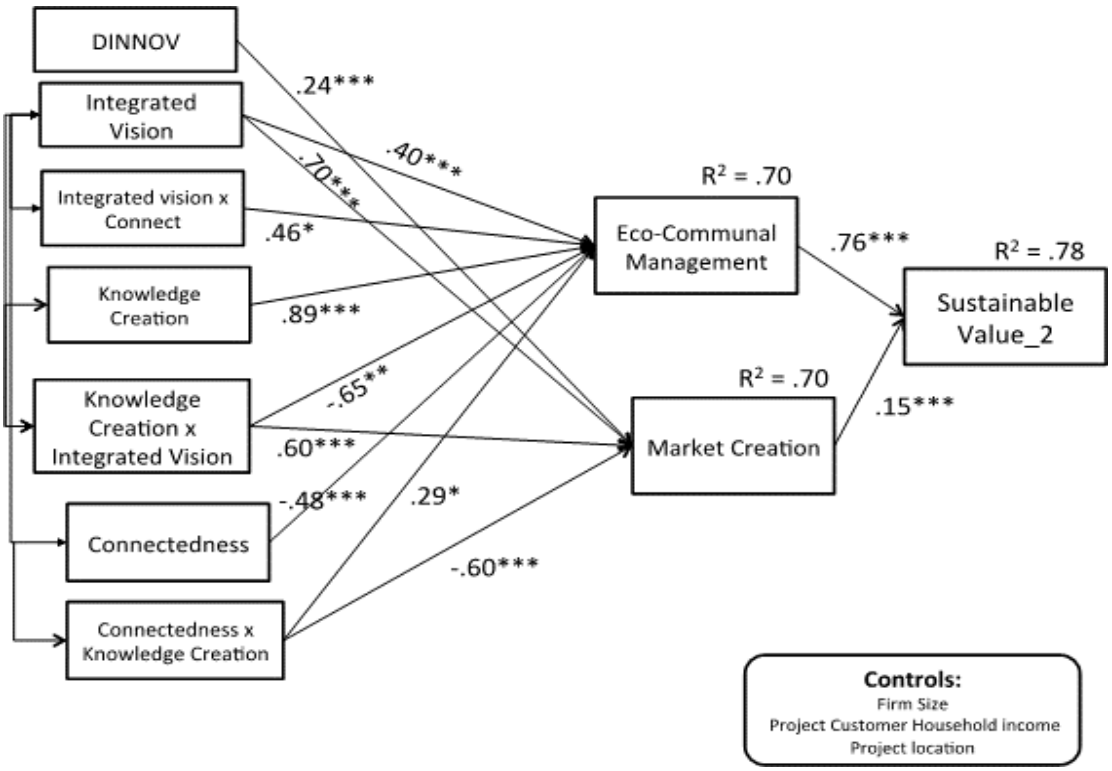
As can be seen above, all of the antecedents had substantial and significant impacts on the mediators, and the mediators had significant and substantial impacts on the outcome.

Hypotheses Test Results

As we predicted, Hypothesis 1 was supported (β = 0.24, p < 0.001), indicating that disruptive innovation had a significant and substantial positive impact on eco-communal management. Hypotheses 2 and 3 were also supported, with a positive and significant relationship between integrated vision and eco-communal management (β = 0.40, p < 0.001), and an even stronger relationship between integrated vision and market creation (β = 0.70, p < 0.001). The test results for Hypothesis 4 further highlighted the importance of knowledge creation in creating markets for RE businesses in developed economies. The strongest relationship coefficient was 0.89, which was highly significant (β = 0.89, p < 0.00).

However, our prediction regarding the relationship between connectedness and eco-communal management (Hypothesis 5) was not supported. Contrary to our expectation, the relationship was negative, with a highly significant beta of -0.48 (β = - 0.48, p < 0.001).

Figure 2. SEM Results for Disruptive Innovation's Effects on RE Outcomes in Developed Economies



*** < 0.001, ** < .01, * < 0.05

Consistent with our predictions, Hypotheses 6 and 7 were supported, with β = 0.76, p < 0.001 and β = 0.15, p < 0.001, respectively. These values confirm that eco-communal management and market creation had significant and substantial positive impacts on the

outcomes of renewable energy businesses in developed economies, as measured by sustainable value. A summary of the hypotheses test results is presented in Table 3. Further verifying the robustness of the model, the predictor variables were found to explain 78% of the variance in the outcome variable.

Table 3: Summary of Hypotheses Test Results

Hypothesis	Path	β	p	Supported?
H1	DINNOV -> MKC	0.24	***	Yes
H2	IVN -> EcoComMng	0.40	***	Yes
H3	IVN -> MKC	0.70	***	Yes
H4	KC -> EcoComMng	0.89	***	Yes
H5	Connect -> EcoComMng	-0.48	***	No
H6	EcoComMng -> SV2	0.76	***	Yes
H7	MKC -> SV2	0.15	***	Yes
*** p < .001, ** p < .01, * p < .05, ns ≥ .05				

In developed economies, the primary path for creating sustainable value for RE businesses is underpinned by knowledge creation; through eco-communal management, key management strategies of commercial enterprises are deployed to enhance business outcomes, improve competitive positioning, and meet market demands for integrated economic, ecological, and social benefits (Hart & Dowell, 2010; Schaltegger & Wagner, 2011). Knowledge creation, which includes technological and business model innovations, opportunity recognition, value creation, and socio-ecological knowledge all shape the management strategies employed by these types of businesses, and in turn have significant and substantial implications for the desired business outcomes (Hitt, Ireland, Sirmon, & Trahms, 2011).

KEY FINDINGS

Value creation for RE businesses in developed economies is undergirded with knowledge creation and translated into desired outcomes via eco-communal management. Knowledge creation includes both entrepreneurial and tacit knowledge, opportunity recognition, value creation, and socio-ecological information, all of which are adaptive and complex. Innovative strategic management based on emergent and systemic knowledge creation improves the competitive positioning of these types of businesses and creates symbiotic and synergistic relationships among return on investment and environmental and social benefits (Armitage et al., 2008).

Disruptive innovation and integrated vision have significant and substantial implications for market creation, resulting in market creation having a positive impact on sustainable value (SV2). Hence, it is imperative for RE businesses to engage in emergent technological and business model innovations, accompanied by appropriate sustainable marketing orientations that are congruent with the DNA and business rationale of the firm and its placement in this dynamic socio-technological landscape (Kumar et al, 2011).

Limitations

This research has investigated the implications of disruptive innovation, integrated vision, connectedness, and knowledge creation on entrepreneurial engagement and RE

business outcomes in developed economies. As such, the model developed here must be verified for contextual applicability (i.e., generalizability and transferability) before it is utilized in other sectors.

Future Research

In light of the emergent and fast-paced technological and business model innovations that are part and parcel of the cyber-physical-biological landscape, the implications of disruptive innovations and knowledge and market creation on creating sustainable value in the RE space (and other businesses) is of paramount importance for entrepreneurs and established businesses alike. Hence, the current research framework and model could be modified and applied to other emerging business opportunities to optimize the configuration of innovation input (i.e., technology and business model) and management approaches to create sustainable value for all stakeholders.

ABSTRACT

Student retention has been a persistent concern of institutions of higher education. Theory postulates that student peer and institutional engagement are significant influences of retention. Our study quantifies student peer engagement by measuring their networking in co-curricular activities, and develops a model that can successfully predict student retention.

KEYWORDS: Peer Engagement, Critical Time Period, Graph Modelling, Student Retention, and Regression

INTRODUCTION

Student retention remains a continuing concern of higher educational institutions, and with recent years seeing an increasing number of students leave college before completing their degree or taking longer to complete their program. According to (Berkner, He & Cataldi, 2002), students at a traditional 4-year institution complete their baccalaureate degrees over a six-year period, while in 2013, 41% did not finish college within six years. Another study found an attrition rate of 20% for students just after one year in an institution (Zobel, 2016). Researchers have identified factors that influence retention including financial status, demographic characteristics, academic performance, and using these factors, built models that are used to predict those most likely to attrite (Delen, 2010). These factors are readily quantifiable and used for predictive models than some other factors. In particular, Tinto (2006) theorizes that institutional engagement and student peer engagement are primary influences of student retention. The concept of student peer engagement has been studied in various forms such as a peer learning (Davies & Barak, (2013). However, according to the National Association of Student Personnel Administrators (NASPA), student engagement is often overlooked in prediction of student retention (Burke, Parnell, Wesaw & Kruger, 2017). Our research focuses on student peer engagement. This form of engagement can be defined as the ability to develop relationships with others and a means to promote connectedness (Sagenmüller, 2018). Between institutional and peer engagement, peer engagement has been studied less frequently, possibly because it is particularly difficult to quantify. In this paper, we study student peer engagement and evaluate its' impact on retention. Our approach leverages the social network perspective (Wasserman & Faust, 1994) where we identify, measure and evaluate interactions of actors in the form of student engagement. Here, we measure engagement in the form of degree centrality which we

track over time to determine its' impact on student retention. We postulate that when students engage with others, the quality of their academic experience improves, which helps to increase student retention (Sagenmüller, 2018). We measure peer engagement over time and aim to identify key time points in a student's career that can be used as stepping-stones to predict student retention and support institutional decision-making.

METHODS

This section presents a detailed description of our methodology as used in this study.

Data Description

The data used in this study was obtained from the Management Achievement Program (MAP). MAP is a requirement for all undergraduate students in business administration at a state university. This program which started in Fall 2006, is designed to engage participants in cocurricular activities, in contrast to the assimilation of content delivered only through lectures or seminars. Students in MAP are required to select and participate in events and activities designed to build professional and career skills. Among the types of events and activities regularly offered are career workshops, seminars, forums, company visits, presentations by senior executives, student clubs, and service learning activities such as volunteer work. Each MAP event offers a number of miles depending on the involvement and initiative it requires. Upon admission into the college, each participant's record is assessed to determine the number of MAP miles that will be required to graduate. Over the course of their study, a student's attendance of MAP events is captured and recorded. Table 1 illustrates a sample of the attendance records.

Table 1: Management Achievement Program (MAP) Sample Attendance Records

Student ID	Student start semester	Event	Event Type	Event Date	Event Miles
21425	Fall 2010	Building Team Pride and Purpose	Workshop	8/24/2010	50
21425	Fall 2010	InterviewTrak Seminar	Seminar	8/5/2010	50
21425	Fall 2010	Information Systems Club Membership	Student Club	10/1/2010	50
21425	Fall 2010	Speaker from Staples – Using analytics for pricing decisions	Seminar	9/24/2010	50
21425	Fall 2010	Mock Interviews with IS Executives	Career Cafe	10/22/2010	50
52129	Spring 2009	Boston Globe company tour – How analytics are used	Company tour	3/26/2011	75
52129	Spring 2009	Leadership Workshop	Workshop	2/12/2011	75
47874	Spring 2010	Interviewing success	Workshop	5/24/2010	50
47874	Spring 2010	Myers-Briggs/Joyce Morgan	Workshop	9/18/2010	75
47874	Spring 2010	Prep for Career Fair	Career Cafe	10/4/2010	50
54644	Fall 2008	Microsoft speaker series	Seminar	12/8/2010	50
54644	Fall 2008	Spring 2009 Career Expo	Workshop	5/19/2011	100
54644	Fall 2008	Career Exploration workshop	Workshop	10/14/2010	50
54645	Fall 2008	Dynamic Resumes	Workshop	10/20/2010	50

For our experiments, we select de-identified unlabeled data from Fall 2006 to Spring 2016 with a total of 46,521 MAP attendance records. This data captures students who have completed the program and others who are still in progress based on their starting semester. We utilize the

unlabeled data to model student interactions in the form of a graph, which we then use to evaluate student peer engagement over time.

Measuring Student Peer Engagement

We measure student peer engagement by their networking at MAP events. We model their interactions as a graph G = (N, E), where N is the number of nodes in the network, and E is the number of edges such that $a_{ij} = 1$ if nodes i and j are connected by an edge, and $a_{ij} = 0$ if otherwise. For this we create graphs by identifying links between students based on similar events that they have attended. Thus each student represents a node and the event establishes the link between two nodes to form an edge. Our goal is to determine degree centrality which is defined as the number of adjacent nodes (Freeman, 1979; Kosorukoff, 2011). We use degree centrality to indicate the level of connectivity amongst students, and thus a measure of student engagement. In this study, we consider an unweighted graph where the nodes and edges are not assigned weights. Hence, if a pair of students have one or more events in common, only a single unweighted edge is established. Figure 1 shows an example of how degree centrality is determined.

Figure 1: Degree Centrality as Student Engagement

	N1	N2	N3	N4	N5	N6	N7	N8	N9	N10
N1	0	1	1	0	0	0	0	0	1	1
N2	1	0	0	0	1	0	1	1	0	0
N3	1	0	0	1	0	0	0	0	0	1
N4	0	0	1	0	1	1	0	0	0	0
N5	0	1	0	1	0	1	0	0	0	0

N8	0	1	0	0	0	0	0	0	0	0
N9	1	0	0	0	0	0	0	0	0	0
N10	1	0	1	0	0	0	0	0	0	0

	N1	N2	N3	N4	N5	N6	N7	N8	N9	N10
N1	**4**	0	0	0	0	0	0	0	0	0
N2	0	**4**	0	0	0	0	0	0	0	0
N3	0	0	**3**	0	0	0	0	0	0	0
N4	0	0	0	**3**	0	0	0	0	0	0
N5	0	0	0	0	**3**	0	0	0	0	0
N6	0	0	0	0	0	**2**	0	0	0	0
N7	0	0	0	0	0	0	**1**	0	0	0
N8	0	0	0	0	0	0	0	**1**	0	0
N9	0	0	0	0	0	0	0	0	**1**	0
N10	0	0	0	0	0	0	0	0	0	**2**

Figure 1 (a.) shows an undirected network with students as nodes and the shared events as edges. Figure 1 (b.) shows an adjacency matrix as a square matrix representing node connectivity where 1 represents an edge between two adjacent nodes and 0 otherwise. For example, N1 and N2 are connected as portrayed by 1 and N1 and N4 are not connected as portrayed by '0'. Figure 1 (c.) shows a diagonal matrix where the number of adjacent nodes are summed up into degree centrality. For example, N1 has a degree of 4, as does N2, N3 has a degree of 3, and so on.
We capture degree centrality over time for each student. Here we analyze student peer engagement per academic year that they are enrolled in the institution. We also take into consideration that an academic year may vary for students based on their starting semester. For example, students starting in Fall will have an academic year of Fall – Spring, while students starting in Spring will have an academic year of Spring – Fall. Our objective is to evaluate the impact of student engagement on retention for varying cohorts of students. It should be noted that a student can attend zero or more MAP events during an academic year. Also, if a student attended an event by themselves (which is very rare) then there is no peer engagement, and thus these records are eliminated from the analysis.

Predictive Model

In order to evaluate the impact of student peer engagement on retention, we first process the de-identified unlabeled data in Table 1 to determine if a student is retained or not which is based on a function of the Map Miles Requirement and the Total Event Miles acquired throughout their enrollment in the institution. Hence, we assign a binary value to each student to indicate retention and attrition, where "Yes" is for a student who meets a given threshold for the Map Miles Requirement and is retained, and "No" for otherwise. Table 2 provides a sample of the labeled data as used in this study.

Table 2: Management Achievement Program (MAP) Sample Labeled Data

StudentID	Starting Semester	MapMiles Requirement	TotalEventMiles	Retained
21425	Fall 2010	250	250	Yes
52129	Spring 2009	1000	150	No
47874	Spring 2010	250	175	Yes
54644	Fall 2008	250	200	Yes
54645	Fall 2008	500	50	No

In order to predict student retention, we utilize logistic regression where our goal is to determine what level of engagement is critical to retention. We select a set of independent variables, which include the MAP Miles Requirement as a categorical variable representing 250, 500, 750 and 1000 miles respectively based on a student's MAP requirements. We also select the degree centralities per student captured over time (per academic year) as continuous variables. The dependent variable is a binary variable representing Yes or No for retention.

Given that the starting semester for students varies, our approach accounts for these variations because it is important to evaluate retention levels for students in similar cohorts. Hence, we

consider a sliding-window approach where we eliminate any times prior to the official starting semester for each cohort and as a result, develop several models based on starting semester. For example, for students who started in Fall 2006, we have 10 academic years, for those who started in Fall 2007, we have 9 academic years, for Fall 2008, we have eight academic years, and so on. Following this, for each cohort of students with the same starting semester, we select the MAP miles required, and then select their degree centrality over time.

Furthermore, any student who participates in an event prior to their official starting semester as well as any students whose starting semester was before the inception of MAP are eliminated from the model. It should be noted however that these students are included when determining centrality because they do contribute to others' engagement.

Potentially Significant Predictors

With varying student participation over time, the resulting matrix is sparse because some students attend MAP events within a short time window while others may spread them out and thus take longer to complete MAP requirements. Our assumption is that such variability is key in identifying critical time periods that may be essential in determining how early retention can be predicted based on the level of engagement within specified time windows. Hence we evaluate the correlation of each time period to retention. Here we study the correlation between the independent variables representing each academic year respectively in association to retention. Hence, given an alpha of 0.05, Tables 3 shows a summary of p values obtained for all academic years for each cohort of students.

Table 3: Correlation Analysis for Degree Centrality Over time

	Spring 2007	Fall 2007	Fall 2008	Fall 2009	Spring 2010	Fall 2010	Spring 2011	Fall 2011	Spring 2012	Fall 2012	Spring 2013	Fall 2013	Spring 2014	Fall 2014	Spring 2015	Fall 2015

AY6	0.66	0.06	0.44	0.00	0.73	0.52	1.00									
AY7	0.09	0.18	0.22	0.06	1.00											
AY8	1.00	0.53	1.00													
AY9	0.66	1.00														
AY10	1.00															

Our findings in Table 3 indicate that across cohorts, starting with the first year of a student's career there is a high level of correlation between peer engagement and retention. This is portrayed by the p values <=0.05 (which are highlighted) in Table 3. It should be noted that for groups starting in Fall 2006, Spring 2008 and Spring 2009, no significant time periods were identified and are thus eliminated from the Table 3.

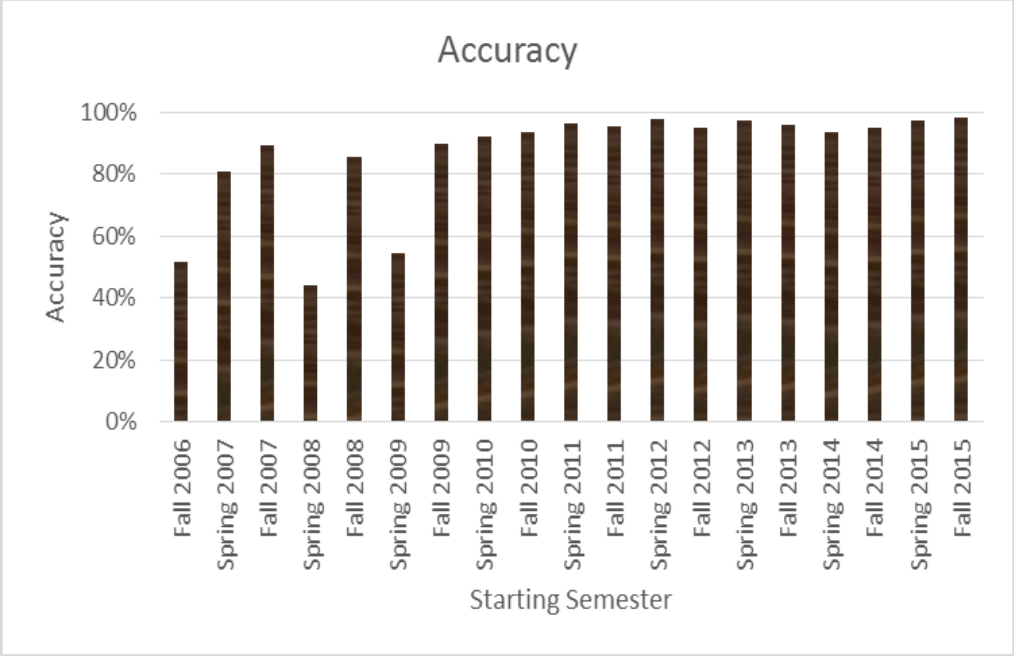
RESULTS

For our analysis, we evaluate our model using accuracy which captures if instances are classified correctly, and Receiver Operative Characteristic (ROC) curve's Area Under Curve (AUC) which aims to capture overlaps between classes. We present our findings based on the starting semester to represent the varying student cohorts.

Evaluation of Accuracy

Here we evaluate the level of correctly and incorrectly classified instances for retention for each cohort of students.

Figure 2: Evaluation of Accuracy for Predicting Retention for Varying Cohorts



Our findings in Figure 2 indicate high accuracy for predicting retention based on student engagement. This is observed for most student cohorts where the accuracy for our model is >= 80%. A high level of accuracy points to the ability of our model to correctly label instances as retained or not retained respectively. On the other hand, for those cohorts that started in Fall 2006, Spring 2008 and Spring 2009, the performance of the model indicates accuracy levels <

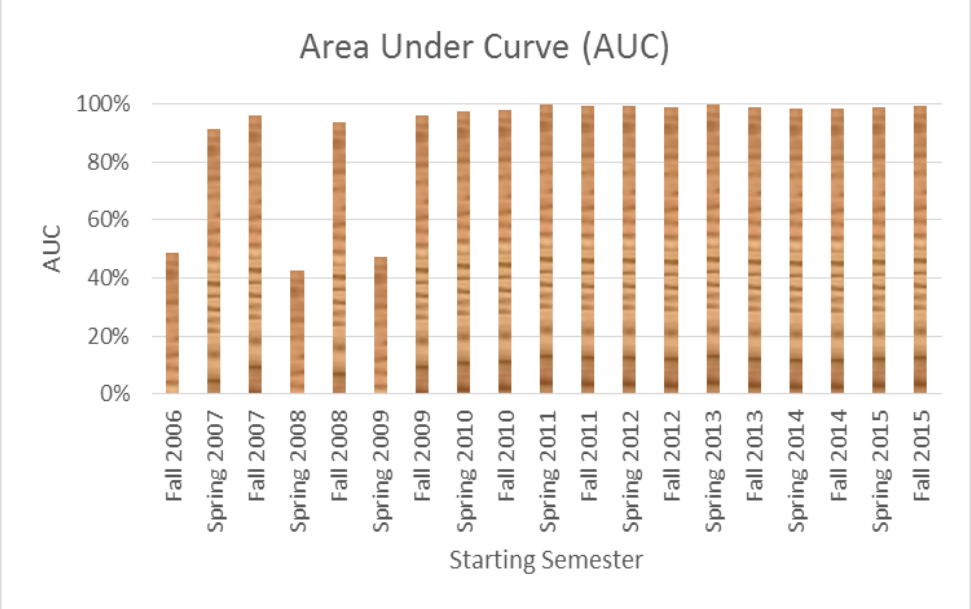
60% which is lower in comparison to other cohorts. In this case, our model aligns labels for retained to non-retained cases and vice versa.

Evaluation of Area Under Curve (AUC)

Here we evaluate the area under curve for the Receiver Operative Characteristic (ROC) curve to determine overlaps between retention and attrition for each cohort of students.

Our findings in Figure 3 indicate area under curve (AUC) levels > 80% which signifies a clear distinction between cases of retention and attrition in our model. However, for those student cohorts starting semesters of Fall 2006, Spring 2008 and Spring 2009, we observe high overlap between the two classes of retention and attrition as indicated by lower AUC < 60%. This overlap can be attributed to similar behavior in engagement observed between retained and non-retained students within these cohorts. Our findings for AUC follow a similar pattern to our findings in accuracy shown in Figure 2.

Figure 3: Evaluation of Area Under Curve (AUC) for Predicting Retention for Varying Cohorts



DISCUSSION AND CONCLUSIONS

Our approach is based on evaluating the level of student peer engagement over an academic year period and its' impact on retention. Student engagement is measured as the number of

peers a student interacts with during academically oriented co-curricular activities or events during their academic career. Our findings indicate that even the first year of student participation in co-curricular activities are critical to student engagement and thus significant determinants of retention. Based on these and our initial results, we believe that we have a strong base to further evaluate student engagement through co-curricular activities as an influencing factor in student retention and develop predictive models with an even higher level of accuracy. For our future work, we would like to drill down into an academic year and evaluate student engagement at the semester level and its' impact on retention.

ABSTRACT

This paper links the research streams of service-dominant logic, service ecosystems, and mobilization, and uses a multi-case study that looked at the service ecosystems of the inward investment agencies of Taiwan, Singapore, and Korea, to investigate how key actors were motivated by the inward investment agencies, and how the emergent systems were mobilized and coordinated, evolving towards mature service ecosystems. The research findings permitted us to enrich the understanding into ecosystems from a mobilization perspective. We were also allowed to develop implications for practitioners as well as policy makers.

KEYWORDS: Service systems and operations, Ecosystem, Mobilization, Service-dominant Logic, Resource Integration, Value Co-creation, Case Study

INTRODUCTION

With decades of development, the sharing of individual resources for others (Belk 2014, Sundararajan 2016), have vividly marked the business and economic environments nowadays. Facing the drastically changing environments, value co-creation has emerged as a dominant logic that determines the strategic advantage of firms and organizations and their resulting survival and prosperity (Prahalad and Ramaswamy 2004, Vargo and Lusch 2008, Kohtamäki and Rajala 2016). Within the emerging paradigm of value co-creation, the development of "ecosystems" has attracted increased attention from scholars, policy makers and practitioners (Moore 1996, Iansiti and Levien 2004, Winn and Pogutz 2013, Lusch, Vargo et al. 2016).

Emphasizing the symbiosis of interconnected and interdependent actors, an ecosystem not only prescribes the scope of a firm's action but also provides important ingredients on which the firm's operation relies (Ansari, Garud et al. 2016). Being able either to develop an ecosystem or to leverage ecosystem advantage thus becomes a pivotal issue. Despite its importance, the present understanding into ecosystems remains constrained, particularly in terms of how actors and subsystems are attracted, linked and coordinated in the emergence of an ecosystem. The extant literature of value-based ecosystems tends to focus attention on resource integration across organizational boundaries (Jaakkola and Alexander 2015, Frow, McColl-Kennedy et al. 2016, Vargo and Lusch 2016), but neglects the fact that actors who contribute their resources in interaction need to be mobilized and coordinated so that they could enact their roles on performing adequate activities in the co-creation practices. Additionally, although an ecosystem can be seen as aggregation of interconnected systems or subsystems (Vargo and Lusch 2011,

Akaka, Vargo et al. 2013, Porter and Heppelmann 2015), few efforts are devoted to investigate how these subsystems are mobilized and coordinated to shape an ecosystem.

Due to the increasing importance of foreign direct investment(FDI) to economic growth and the global competitions, many countries have established national inward investment agencies to provide services in recruiting new investment, removing investment obstacles, and facilitating administrative process for investment. To function efficiently and effectively, those national inward investment agencies, though in the past have simpler structure and network, nowadays tend to operate through single-window mechanism with wilder participation of stakeholders across foreign and domestic, private and public sectors, which created more complicated service ecosystems. Previous research stream in this field was few and only looks at the network from perspectives of traditional marketing theories, such as place marketing (Kotler, Hamlin, Rein & Haider 2002). As the changes in the characteristics of the ecosystems surrounding those inward investment agencies causing by environmental challenges such as global competition, there is a need to look at the services systems from new perspectives.

As a result, this paper aims at exploring the mobilization process in the emergence of service ecosystems. We drew a linkage between the research stream of service-dominant logic (e.g. Vargo and Lusch 2017), existing studies of business ecosystems (e.g. Iansiti and Levien 2004, Winn and Pogutz 2013), and the literature of mobilization(e.g. Möller & Halinen 2017, Bockhaven & Matthyssens 2017), to lay the theoretical foundations. We explored this research issue through a multi-case study that looked at the emergence process of the ecosystems of Inward investment agencies of Taiwan, Singapore, and Korea. Those cases, with a time-span of five years, detailed the development process of how key stakeholders, including foreign and domestic companies, institutional investors, private and public organizations, were motivated by the national single-window platforms of Inward Investment agencies, and how the emergent systems were mobilized and coordinated, evolving towards mature service ecosystems. The research findings permitted us to enrich the understanding into ecosystems from a mobilization perspective. We were also allowed to develop implications for practitioners as well as policy makers.

LITERATURE REVIEW

Literature Review of Mobilization

Previous Research Streams of Mobilization

Previous researches have explored how business actors can tackle the behavioral challenges faced when they introduce radical innovations that go against the institutionalized rules, interests and logics of their field. Often, such innovations get stuck on the unwillingness of actors, other than customers or users, to adopt or accommodate the innovation (Adner & Kapoor 2010). Resistance arises because the innovation infringes on actors' behavioral drivers such as shared meanings, identities, interests and influence structures, and thus unsettles the consensus within an existing field. Because of this dynamic, scholars investigating the genesis of (radical) innovations by intentionally governed networks of business actors – the strategic nets view – have turned to studying the development of business fields (Moller & Svahn 2006). Unlike markets, such fields acknowledge the role of not just the players directly involved in value creation and exchange from the innovation – the value-creating system (VCS), – but also that of the outsiders influencing it, even before a market is formed (Möller & Svahn 2009). To get the innovation adopted therefore involves a need to “move” the surrounding field – the aggregation of all the relevant actors connected to the value creation process, the cultural, normative and

regulative principles governing their behavior and the network inter relating them (DiMaggio & Powell 1983; Kenis & Knoke 2002) – toward a new consensus (Vargo,Wieland & Akaka 2015). To move a field implies a challenge to mobilize actors and to guide their sensemaking (Möller & Svahn 2009; Dimaggio 1988). All relevant interdependent actors need to be convinced of the innovation's value, and their diverse interests aligned (Mouzas & Naude 2007; Öberg & Shih 2014).

In mature fields, these behavioral processes arguably constitute the main challenge for the adoption of radical innovation – warranting a strategic analysis of their own. Innovation originates outside the conformist center of such fields, and thus imports divergent logics that conflict with deeply institutionalized habits, norms and regulations (Rao, Morrill, & Zald, 2000; Van Bockhaven, Matthyssens, & Vandenbempt, 2013). This is especially true in a services system surrounded around the inward investment agency of a country when facing challenges outside the center, such as global competitions, internal and external forces (Kolter, Hamlin, Rein &, Harder 2002). Innovation success is constrained by the diverse interests of numerous players, highly professional factions with limited accountability for outcomes and extensive government-led regulatory and funding influence (Herzlinger 2006). Still, the strategic nets framework focuses mainly on the information and capability needs to develop the VCS, such as the capabilities which need to be mobilized and the coordination mechanisms and structures sustaining mobilization (Partanen & Möller 2012). It recognizes the need for agenda-setting, bargaining and contracting to enable mobilization (Möller 2010; Mouzas & Naude 2007). Yet, it has not yet examined in sufficient analytical detail the dialectical (reciprocally contested) processes of actor mobilization and how they might be steered by the mobilizer.
Previous investigations into the dialectics of actor mobilization have borrowed from more socially-focused lenses such as institutional (Brito, 2001; Ritvala & Salmi 2010), social networks (Araujo & Brito 1998), stakeholder and social movement theory (Ritvala & Salmi 2011). Since the latter two are especially cited for the analysis of the micro-foundations of collective agency (Rowley & Moldoveanu 2003), following research use them to enrich the strategic nets analytical frameworks for mobilization. By breaking down the business actor's network mobilization problem into three challenges, the most fitting theoretical perspective is introduced to analyze it for per challenge: stakeholder theory to identify the players; social movement theory to align and mobilize collective action and strategic nets with a focus on business actors as mobilizers.

1. Stakeholder Analysis
   The Gold Standard for Actor Identification: Stakeholder Analysis Tools

Stakeholder theory is a quite influential framework to explain actor dynamics, drawing attention to the diverse and self-interested groups of actors that affect or are affected by a firm's strategy (Freeman 1984). It has the merit of bringing stakeholders' reactions to firms' strategies into the equation for network strategizing, based on whether their interests align or conflict (Freeman 1994; Rowley & Moldoveanu 2003). To this end, stakeholder literature has developed analytical tools to identify, prioritize, and assess the demands of stakeholders.

Stakeholder analysis starts with the identification of relevant stakeholders, actors who can affect, or who are affected by, the firm's activities, something that is especially true of those with power, or a demand that is seen as urgent or legitimate in the eyes of the broader public (Mitchell, Agle, & Wood 1997). Based on these elements, one can map the relevant actors on what is likely the most well-known stakeholder management tool: the interest-power grid (Freeman 1984). This framework is a response to the complexity of dealing with the differing demands of multiple stakeholders. It helps to prioritize stakeholders (i.e., those who are high in

regards to interest and power ought to receive more attention) and differentiate the ways of involving them in decision-making (Frooman 1999). Further analytical contributions for network mobilization from the stakeholder framework consist mainly of more dimensions to differentiate how stakeholders should be treated. Introducing a social movement lens to stakeholder identification, Rowley and Moldoveanu (2003) point to how identity further explains situations when stakeholder groups act irrationally in relation to their interests. In their model, stakeholders act against their interest if they value a common identity that favors mobilization, and they will not defend their interest when such threatens the integrity of a valued group identity.

Others point to the importance of not just mapping stakeholders on an interest-power grid, but also of taking into account the coalitions and relationships between them (Frederick, Post, & Davis 1992). In a comprehensive evaluation and elaboration of stakeholder identification tools, Ackermann and Eden (2011) further mention the possibility of using stakeholders' dispositions toward a strategy (positive or negative), and of drawing their full network of (in)formal 'influence paths' – the visualization of net dyadic influence relationships between stakeholders as directional arrows – to assess centrality (Rowley 1997). Such a visualization helps the formulation of pathways toward mobilization targets.

Stakeholder theory opens the analysis of external actors to the dialectics of reciprocal self-interest. However, it only examines the outcomes that fit the 'unidirectional' and competing self-interest of either the firm or its stakeholders separately (Donaldson & Preston 1995). Stakeholder theory automatically assumes a kind of bargaining mode and disregards mutually beneficial shared goal achievement. With a repertory based on bilateral claims, rights and justice, it focuses on how much value is captured by each party and neglects how stakeholders and firms can co-create value toward a joint outcome as one VCS (Priem 2007). Given stakeholder theory's conflict ontology and dyadic focus, its tools have a limited appreciation of collective dynamics and outcomes. So, whereas stakeholder theory offers perhaps the furthest developed analytical tools for stakeholder identification, and prioritization, it does not delve into how to mobilize for a shared interest.

2. Addressing the Collective Alignment Challenge: Social Movement Mobilization Foci

Mobilization and the pursuit of collective outcomes do take center stage in social movement theory. It studies the bottom-up collective action of interest groups striving for social change – social movements. Its empirical tradition focuses on three interrelated tactics enabling such collective action: resource mobilization (McCarthy & Zald 1977), issue framing (Benford & Snow 2000) and political opportunity processes and structures (Goodwin & Jasper 1999; Kriesi 2004). Their analytical contributions to the mobilization process lie mostly in specific mechanisms that promote the alignment and active participation of disparate actors toward a co-constructed shared interest (Klandermans 2004). This mobilization process consists of a diagnostic (problem identification), a prognostic (solution identification) and a motivational (stimulation of action) task (Benford & Snow 2000). Whereas the stakeholder frameworks offer managerial tools for the diagnosis of current actor interest, power and identity barriers to collaboration, the three social movement tactics aim to achieve momentum in promoting a solution.

The first tactic, resource mobilization focuses on the strategic use of material resources, human actors (McCarthy & Zald 1977), organizational cadres and resources (Jenkins 1983), as well as the concepts of moral legitimacy and support (Cress & Snow 1996), and cultural resources such as field embedded vocabularies, conceptual tools, prior activist experience and contextualized understanding of the issue (Edwards & McCarthy 2004). It considers how these resources can address social movements' problem of inducing participation for collective action.

Secondly, social framing captures movements' construction, legitimation and support gathering for a collective identity (Goffman 1974). Frames are “purely individual cognitive structures or mental schemata” (Snow 2004), and much of this work investigates how these frames become widely adopted. These politicized processes contain both a discursive component, as well as cognitive strategies to attract and align a critical mass using for alignment processes of strategic framing (Benford & Snow 2000). The latter offer the mobilizer certain analytical clues for action to gain resonance with a targeted group. Frame bridging involves linking the mobilizer's frame toward sentiments shared by a separate group (Gerhards & Rucht 1992). The frame can also be amplified by clarifying and emphasizing the norms that it stands for (Snow, Rochford, Worden, & Benford 1986). Frame extension implies that movements enlarge their repertory of issues, symbols or values to also attract yet unmobilized groups, for instance such as if a PM network would emulate the vocabulary of nutraceuticals to move them toward personalized active foods. Frame transformation aims for frame reinstitutionalization in the broader field by over-turning, renewing or replacing old beliefs, meanings and myths (Benford & Snow 2000; Veugelers 2011).

A third tactic elaborates how social movements' political-cultural context, their organizing structures and contentious processes spark and constrain collective action (Tarrow 1996). This strand contributes how mobilizing actors can make use of preexisting formal and informal structures (McAdam & Scott 2005; Tilly 1978) and contextual opportunities. The latter may consist of adversaries' weakened ability to oppose or the focus of mass media, public figures or other channels to broadcast the issue of interest (King 2008b; Kriesi 2004). The tactics mainly boil down to identifying weaknesses or opportunities in outsiders' situations, and ways to leverage and exploit one's own social or organizational capital (Koopmans 1993). The concrete analytical foci of this concept are the attention to influential intermediaries, coalition building and for the timing and adaptation of mobilization strategies to match the readiness of the field to actually receive them (King 2008a).

Although social movement theory is the most widely used framework for mobilization analysis, the mobilization process and goal are different for business actors and societal interest groups (Hart 2004). The main discrepancies reside in the primary goals (commercial self-interest vs. a shared group interest), incentive structures (employees are paid, unlike voluntary movement members), and interpretation (different vocabularies, outcome aspirations and relational norms) (Laursen & Andersen 2016; Polsky 2000; Selsky & Parker 2005). Social movement theory assumes an assimilation of self-interest with that of the collective and does not really consider the continuing influence of individual interests, which is a cause of concern when members have profit-seeking motives. Thus, mobilization by a for-profit actor comes with specific challenges.

3. Mobilization by Business Actors: Contributions of Strategic Nets

To explain a business actor's analytical challenges as mobilizer, Bockhaven & Matthyssens (2017) adopts and extends the strategic nets perspective's focus on the classification, dynamics and structure of deliberately created and managed – thus strategic nets. The latter are coalition networks of organizations that are linked in a VCS involved in the commercialization of a joint product or service output (Moller & Svahn 2006). The framework specifically contributes to our understanding of how networks can be (partially) governed by network orchestrators or mobilizers (Halinen, Salmi, & Havila 1999; Mouzas & Naude 2007; Paquin & Howard-Grenville 2013). In this network agency perspective, mobilization is a micro-level sub-process in the early stages of the meso-level field emergence process (Araujo & Brito 1998; Möller, 2010; Möller, Rajala, & Svahn 2005). This is when an ‘emerging business net’ (a strategic net aimed at radical

innovation changing or creating a field) forms around a new dominant technological design (Möller & Rajala 2007). The perspective's contribution to mobilization analysis lies mainly in the recognition of the mobilizer's responsibility to envision a new VCS, to engage with other actors' mental models, and to pay attention to interdependencies within the current and the new VCS. The mobilizer's analytical challenge in this perspective can be broken down into four tasks that focus mainly on cognitive strategies and capability needs.

A mobilizer's first task is recognizing and making sense of the new VCS architecture (Moller & Svahn 2006) by developing a mental model of it, consisting mainly of vague ideas and affective intuitions (Hill & Levenhagen1995). Envisioning a new VCS amid unsettled positions, and before a market has formed, is enabled by one's network picture (actors' situated understanding of their activities in the net), and by spanning actor categories for exposure to diverse ideas and perspectives (Möller & Svahn 2009; Mouzas, Henneberg & Naudé 2008). The radically new VCS that require field development are characterized by their involvement of a wide range of actors (Aarikka-Stenroos, Sandberg & Lehtimaki 2014). This complex and ambiguous task hinges on the absorptive capacity to recognize, select and focus on the development of a business concept, and to derive the activities and boundaries of the VCS (Möller & Svahn 2009; Partanen & Möller 2012).

The next task lies in developing critical sense-making routines to develop the vision into a clear, adoptable frame that reduces uncertainty and attracts sympathy from others (Ritvala & Salmi 2010). It involves developing the joint heuristic that outlines how value will be created by the entire VCS in the form of business propositions that incentivize relevant actors (Hermes & Mainela 2014; Mouzas & Naude 2007). This implies, besides the ability to envision the VCS, the identification of actors with key roles in the emerging network based on insight into which capabilities are required for the collective goal, and where they reside (Möller & Rajala 2007; Möller & Svahn 2009; Mouzas & Naude 2007). The latter requires an understanding of the logics driving the behavior of different actor categories so that integration strategies can be developed (Brito 2001; Öberg & Shih2014).

Thirdly, mobilizers further reduce uncertainty by communicating a joint network development agenda. This extends the joint frame into a project plan with concrete steps, challenges and activities (Cova & Salle 2008; Möller 2010). Such agenda-setting enables the mobilizer to motivate others to transition from their old logics to seeing the opportunities of the new VCS (Möller & Svahn 2009). To this end, generative learning, to co-construct shared meanings with the emerging network, is required from the mobilizer (Möller & Svahn 2009; Storbacka & Nenonen 2015). Agenda-setting guides actors' recognition of options for action and locks them into a desired investment trajectory (Möller 2010). It also requires trajectories to co-evolve with the network to find common ground on the basis of shared values (Ritvala & Salmi 2010). These trajectories aim to transition actors' logics and incentivize them by using intermediaries (Hermes & Mainela 2014).

This finally opens the path to tackle the convergence of the diverse actors to collaborate in an increasingly committed way (i.e. from jointly acquiring a common resource pool or developing joint rules and standards to more vertical, specialized and hierarchic joint development of actual commercial applications (Brito, 2001; Möller & Rajala 2007)). The task of convergence revolves around bringing the interests, priorities and goals for the interaction of the wide set of actors closer to each other, for an increased impact toward the shared goal (Öberg & Shih 2014). It entails specifying actors' contributions in a stratified manner, according to their intentionality and (in)direct nature (Aarikka-Stenroos et al. 2014; Story, O'Malley, & Hart 2011). This should reveal differences in actors' eagerness and capabilities to contribute to the mobilization process. The

task of active mobilization hinges on the settlement of collaborative coordination rules and structures – often steered by a hub organization – to negotiate the risk, effort and reward shared between network members (Mouzas & Naude 2007; Partanen & Möller 2012). This hub approach helps to manage participants' satisfaction, and it positively influences performance especially of complex networks (Heidenreich, Landsperger, & Spieth 2016).

4. Toward a Business Actor's Analytical Tool Kit for Network Mobilization to Develop a Field

In terms of a mobilization analysis framework for field development by business actors, the strategic nets perspective helps in the sense-making of the new VCS. However, it could be extended with a more elaborate capability for sense-making of the actor dynamics. At the least, it could encompass having to move cross-sector actors to take up a role in the VCS (Araujo & Brito 1998; Moller & Svahn 2006). When it involves business actors co-creating a joint product or service innovation, or like-minded militants who find it rewarding to identify with an interest group, mobilization can be based on a shared interest (Rowley & Moldoveanu 2003). However, when mobilization aims for change at the field-level and thereby spans societal sectors, each with distinct interests and meaning systems, alignment becomes problematic (Polsky 2000; Ritvala & Salmi 2010). Hence, a mobilization analysis framework for business actors should empower the mobilizer to design a mobilization strategy that looks beyond the VCS and cognitions.

Literature Review of Service Ecosystem

The ecosystem perspective, drawing originally on biological eco- systems to describe differences in the nature of industries and also seen as a third mode of economic organizations besides markets and hierarchies (Moore 1993, 1996), has rapidly gained currency in describing collaborative forms of constructing innovations and business coalitions (Adner & Kapoor 2010; Autio & Thomas 2014; Frow, McColl-Kennedy, & Payne 2016). The drawback with the ecosystem's popularity is, as Aarikka-Stenroos and Ritala (this issue) argue is that the term.

"... has become a buzzword, sometimes adding very little to the analysis. Indeed, a critical look at the rapid expansion of B2B studies using the concept reveals that it is used in a variety of ways, ranging from a synonym for business networks to an analogy for interconnected environments, and even to describe a full-fledged theoretical and empirical approach". Aarikka-Stenroos and Ritala (2017) offer an extensive analysis of how different disciplines use the ecosystem perspective. They distinguish business ecosystem, innovation ecosystem, entrepreneurial and start-up ecosystems, platform ecosystem, and service ecosystem literatures, and their sub-categories. Based on a comprehensive literature analysis, the authors suggest two approaches to ecosystems from the network management perspective: "ecosystem as a new layer" to be managed, adding to Möller and Halinen's (1999) framework of network management levels, and "ecosystem as a novel perspective to business networks, which involves providing an update to current business network frameworks."

We see that most authors using the ecosystem term combine the "layer" or domain view and the "perspective" view. When treated as a domain, we should ask what are the differences between "sector/ cluster", "field", "network environment", and "ecosystem"? What new dimensions or characteristics does the ecosystem description provide? It seems that the broad ecosystem applications (ecosystem as a metaphor for industries, sectors, and clusters) assume that the focal domain is composed of interrelated actors having competitive and collaborative relationships and various aims for influencing and even directing the co-evolution of the focal domain. These larger "ecologies" can comprise several interrelated and competing "business

ecosystems" often driven by a hub firm (e.g., Apple's iPhone/iTunes ecosystem, Google's Android ecosystem), and constituting, with an array of technology providers "platform ecosystems" and with even other, non-business actors "mobile phone/services ecosystems". The mobile phone/services ecosystem may be depicted as part of a more extensive ecosystem comprising all electronic and software fields (and their science and research extensions). This simplified example raises the following observations.

First, all domain-type of ecosystem applications can be described through the actors-resources-activities metalanguage, meaning that the IMP network theory can describe ecosystems. Second, the different views on ecosystems overlap with the other labels; more expansive ecosystem applications (ecologies) seem very similar to the business field conceptualization (DiMaggio & Powell 1991; Kenis & Knoke 2002), while most of the more limited applications are analogous to the strategic nets proposed by Möller et al. (2005). This is clear from Adner's (2006, 98) definition of ecosystems as "the collaborative arrangements through which firms combine their individual offerings into a coherent, customer-facing solution." This is a neat way to describe a strategic net. Underlying our hint of irony is the worry that those ecosystem enthusiasts that are not familiar with business and innovation network research (or institutional studies) are reinventing the wheel, a serious problem in social sciences and one that is especially pertinent to the silos of business studies.

This does not mean the ecosystem approach is without merit – quite the contrary. The perspective forces us to develop theoretical tools for deeper understanding of the processes and mechanisms that drive the construction and change of business fields, noting both institutions and technologies as part of them (Adner 2017). Institutional theory and evolutionary economics, together with cognitive and learning theory seem useful sources for more advanced studies. The broad ecosystem studies can contribute to the innovation network orchestration research and vice versa, and it seems clear that the more focal-, hub- or coalition- centered ecosystem researchers would benefit from interaction with strategic nets scholars.

Literature Review of Service-Dominant Logic

Previous Research Streams of Service-Dominant Logic

Vargo & Lusch(2004) outlined a framework that has become known as "S-D logic". The core ideas were rather simple and straightforward. First, marketing activity (and economic activity in general) is best understood in terms of service-for-service exchange, rather than exchange in terms of goods- for-goods or goods-for-money. Second, value is co-created, rather than created by one actor and subsequently delivered. As with all "new" ideas, neither of these was entirely new (c.f. Arthur 2009). For example, Bastiat (1848/1964) had declared that "services are exchanged for services" over 150 years ago. Likewise, Prahalad and Ramaswamy (2000) had been advocating value co-creation for several years prior to Vargo and Lusch (2004) and before them Ramirez (1999) had traced its recognition back at least 300 years. In fact, S-D logic was, from its beginning, more about the identification and extension of apparent coalescence in the ongoing development of marketing thought, as reflected in the title "Evolving Toward a New Dominant Logic for Mar- keting" (Vargo & Lusch 2004; Akaka, Vargo, & Lusch 2012), than a radically new idea. That is, it has been grounded on a foundation built by many others, as has been its progress.

Since its introduction, the development of this integrated framework has continued, first by inclusion of the other (than service exchange) primary activity involved in value co-creation—resource integration—and then by explication of the idiosyncratic and experiential nature of

value (e.g., Vargo & Lusch 2008). More recently, in elaborating this framework, the consideration of the role of institutions in value co-creation has moved to the forefront. All of these developments have been captured in five core foundational premises (FPs, of which there are now a total of 11), which have more recently (Vargo & Lusch 2016) been identified as axioms (see Table 1).

There have been other "turns" that have been somewhat more subtle or at least not fully captured in separate FPs/ axioms—though some have resulted in the rewording of existing FPs—and others are currently in more formative stages. Examples of these are the move to a generic-actor (A2A) orientation and the identification of a service ecosystem as the "unit" of analysis for value co-creation (Vargo & Lusch, 2011). There are others.

Vargo & Lusch (2017) pointed out that S-D logic represents a dynamic, continuing narrative of value co-creation through resource integration and service exchange that has been constructed by an increasingly large number of academics from various disciplines and subdisciplines. During the last decade, service-dominant (S-D) logic (1) has taken a series of significant theoretical turns, (2) has had foundational premises modified and added and (3) has been consolidated into a smaller set of core axioms. S-D logic can continue to advance over the next decade by moving toward further development of a general theory of the market and, even more broadly, to a general theory of value co-creation. To support this theory of the market requires developing more midrange theoretical frameworks and concepts of service exchange, resource integration, value co-creation, value determination, and institutions/ecosystems. These midrange theories can be partially informed by theories outside of marketing, including those under the rubrics of practice, evolutionary, complexity, ecological and structuration theories. Evidence-based research is also needed.

Table 1 : The axioms of S-D logic.

	Axiom
Axiom 1/FP1	Service is the fundamental basis of exchange
Axiom 2/FP6	Value is cocreated by multiple actors, always including the beneficiary
Axiom 3/FP9	All social and economic actors are resource integrators
Axiom 4/FP10	Value is always uniquely and phenomenologically determined by the beneficiary
Axiom 5/FP11	Value cocreation is coordinated through actor-generated institutions and institutional arrangements

Foundations, Bifurcations, and Conceptual Turns

At the heart of S-D logic is the identification of service exchange. Vargo & Lusch (2017) especially noted the primary role of operant resources (such as knowledge and skills) that can act on other resources to create a benefit, rather than the role of the relatively static, operand resources (such as natural resources), which are more commonly considered. The S-D logic solution was a transcending conceptualization of service (a process, usually expressed singularly)—i.e. as noted the use of one's resources for another actor's benefit—that depicted service as superordinate to goods and services (units of output, usually plural). In other words, as Gummesson (1995) had noted some years before, "activities render services, things render services." Given that it is redundant to speak of intangible units of output, called "services," as being created to provide service, the former is generally not a concept used in S-D logic.

Instead, the framework suggests that service can be provided either directly or indirectly (e.g., through a good).

Zooming Out: From Resource Application To Resource Integration

Partly due to the editorial focus of the Journal of Marketing (Vargo & Lusch, 2004), as well as to the latent influence of traditional models, the initial perspective was relatively dyadic and micro-level focused and somewhat managerially oriented. A major turn occurred therefore with the attempt to zoom out to reveal the bigger picture. Initially, that zooming out exposed other actors, at first generally seen as other firms (e.g., "competitors" and "suppliers"). It then extended to customer connections (e.g., family, peers, etc.), all involved in service-for-service exchange, thus, at least part of the broader context (Akaka, Vargo, & Lusch 2013). But closer examination revealed that all of these actors exhibited foundational commonalities in addition to service-for-service exchange—resource-integration activities. That is, the (especially operant) resources used in service provision were both the source and the combined outcome of service-for-service exchange. This led to the identification of FP 9, later designated Axiom 4 (Vargo & Lusch 2008), an FP/Axiom that seems to have resonated particularly strongly among S-D logic scholars and others. It also revealed a network structure (Chandler & Vargo 2011), but one that had dynamic, recursive properties beyond those typically attributed to networks. It was becoming increasingly apparent that the key to value co-creation was the ongoing interplay of resource creation and application afforded through reciprocal exchange and differential access and integration.

Full realization of this dynamism, however, required an additional turn. As we argued in Vargo and Lusch (2011), an essential step toward fully grasping the process and extent of value co-creation is the "need to overcome conceptual problems associated with the notion of a 'producer,' as a creator of value, and a 'consumer,' as a destroyer of value. Briefly stated, all actors (e.g. businesses, individual customers, households, etc.) engaged in economic exchange are 'similarly', resource-integrating, service- providing enterprises that have the common purpose of value (co)creation. This had been partially reflected in the wording of FP9: "all social and economic actors are resource integrators" (Vargo & Lusch 2008) but more fully captured in the somewhat tongue-in-cheek proclamation that "it's all B2B" (Vargo & Lusch 2011), which was subsequently rephrased 'more neutrally' to "A2A" (actor to actor). In addition, it also moved the network orientation to at least a rudimentary conceptualization of a service ecosystem, as will be discussed.

Service Ecosystems

As one zooms out from dyadic interactions and discreet transactions, the first thing noticed is that these dyadic interactions do not take place in isolation, but rather within networks of actors, of which the dyad is just a part. These networks can be seen at various levels of aggregation (e.g., macro, meso, micro). Structurally then, these networks reflect what S-D logic captures axiomatically in the resource-integration specification of Axiom 3. Likewise, they emphasize that the benefit (value) realized by a beneficiary (e.g., a "customer") does not occur in isolation either, but rather through integration of the resources from many sources, thus best understood as holistic experiences (FP9/Axiom3 and FP10/Axiom4).

At first glance, it might appear that there is little new here, just the acknowledgement that service provision, value co-creation and value realization take place in networks, as sociologists Granovetter (1973), Burt (1992) and various scholars in marketing (e.g., Achrol & Kotler 1999) have been telling us for some time. Partially, this would be a correct evaluation. However, the S-D logic framework adds several key characteristics that are not in all cases typical of these

network conceptualizations. Most obvious among these is that the connections represent service-for-service exchange, rather than just connections of resources, people, or product flows; thus, in S-D logic, network actors are linked by common, dynamic processes (service provision). Second, the actors are defined not only in terms of this service provision (resources applied for benefit) but also in terms of the resource-integration activities that the service exchange affords. Finally, the network has a purpose, not in the sense of collective intent but rather in the sense of individual survival/wellbeing, as a partial function of collective wellbeing. The study of purpose or purposeful behavior has a long history in philosophical thought concerning concepts of teleology and, more contemporarily, teleonomy (Pittendrigh 1958). The latter focuses more on complexity, emergence and self-organizing systems (Christensen, Anthony Scott, Berstell, & Nitterhouse 2007), which are crucial characteristics of service ecosystems. This literature fits well as we try to understand how wellbeing of individuals is both contingent on and contributes to a dynamic network, in which the resources of the actors are being continually updated. It also indicates the need for a subtle but significant shift in orientation among actors, away from the primacy of conflict and toward the primacy of cooperation and coordination. Unpacking how this "purposeful," cooperative activity leads to value co-creation will be a major underlying theme for the next 10 years, as will be discussed below.

Institutions

This coordination for value co-creation implies mechanisms for the facilitation of these resource integration and service-for-service exchange activities. As partially discussed in Vargo and Lusch (2016), this is the role of institutions and institutional arrangements. Institutions are the humanly devised rules, norms, and beliefs that enable and constrain action and make social life at least somewhat predictable and meaningful (Scott 2008), what North (1990) calls "rules of the game." Institutional arrangements refer to higher-order assemblages of interrelated institutions (sometimes referred to as "institutional logics"). Thus, S-D logic has recently identified the service ecosystem, partially conceptualized in terms of institutions, as the unit of analysis for value co-creation. Service ecosystems are defined as "relatively self-contained, self-adjusting system of resource-integrating actors connected by shared institutional arrangements and mutual value creation through service exchange" (Vargo & Lusch, 2016, p. 161).

With the addition of institutions and service ecosystems to S-D logic's foundational concepts, we believe S-D logic can begin to be something more than the lens, framework, and perspective, as we have characterized it up to now. That "something more" can take several forms, each with its own potential impact. At a minimum, it affords the completion of a relatively coherent narrative of value co-creation through resource integration and service exchange, coordinated by shared institutional arrangements that de- fine nested and overlapping service ecosystems (see Fig. 1).

Figure 1 : The narrative and process of S-D logic. Note: Vargo and Lusch (2016)

METHOD

Qualitative Research Method

This study employs qualitative research method and uses multi-case study as the research method. The reason why this study applies qualitative research is to explore the questions of "how" and "why". Doing qualitative research depends on researchers' observation on phenomenon and deep interaction with facts so that the meanings of problem will be comprehensively and deeply analyzed and examined to conclude applicable implications. In addition, this research studies "process" which focuses on actors' experiences and developing process of the cases.

Multi-case Study

This research also utilizes multi-case study method by adopting 3 cases including the service ecosystems of the inward investment agencies of Taiwan, Singapore, and Korea to make comparisons. As a result, it helps to do detailed and deep investigation to make comprehensive explanation.

Data Collection

The data that this study collects is from two parts: interviews and secondary data. Six interviews have been conducted, which takes around 7.5 hours in total. The interviewees are from different organizations and different positions. On the other hand, the secondary data includes actors' social network sites, speeches, videos, articles, community newspaper, media and academic reports. All these materials are used to help form thorough understanding of the case and know its developing process and operation clearly.

FINDINGS

1. Taiwan

1.1 Taiwan's Inward Investment Agency- the InvesTaiwan Service Center (ITSC)

In order to provide more business-friendly investment services and attract international firms to invest in Taiwan, the InvesTaiwan Service Center (ITSC) has been established since the year of 2010 under the Ministry of Economic Affairs (MOEA) to offer a single-window for investment services, and uses a "project-oriented, dedicated case manager with specific responsibilities, and customized start-to-finish services" approach to assist investing firms. After understanding the needs of investing companies, the ITSC provides services before, during, and after the investment process, while also taking governments to jointly assist firms in eliminating obstacles to investment, thereby accelerating the completion of investment projects in Taiwan.

The ITSC provides fully customized services to meet companies' investment needs, takes advantages of links to specialized resources, and actively serves as a communication platform between government units, facilitating the joint resolution of investment issues. If a major impediment to investment is encountered, the ITSC will activate its coordination mechanisms and hold a working group conference. If the problem still cannot be resolved, the ITSC will notify the MOEA and Executive Yuan to hold an inter-agency coordination conference. The ITSC aims to swiftly respond to problems, and actively reports back to investors on the progress of its assisting actions; as a result, its service spirit has made it an optimal partner for companies planning to invest in Taiwan.

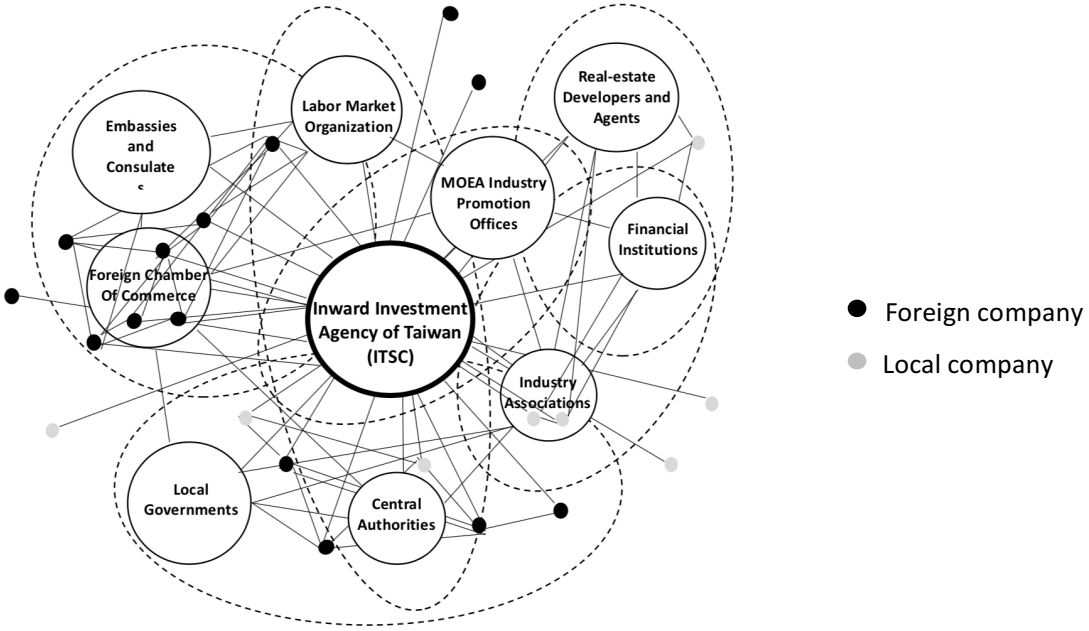
1.2 Investigation into the Service Ecosystem

1.2.1 Stakeholder Analysis

In order to implement the above-mentioned tasks, the ITSC links with various professional resources and related government departments, including actors of 20 MOEA industry promotion committees/offices, 7 industry associations, competent authorities, local governments, foreign and domestic leading enterprises, real-estate developers and agents, financial institutions, foreign and domestic chamber of commerce, Labor market organizations, Embassies and consulates, naturally forming an service ecosystem.

Within the service ecosystem, the main focused actor, the inward investment agency, the ITSC, declaims the value proposition of helping companies to invest successfully in Taiwan, which attracts other actors to participate in the ecosystem.

Figure 2 : The Ecosystem of the Inward Investment Agency of Taiwan



1.2.2 Social Movement Mobilization

Since 2015, the MOEA, the supervisory authority of the ITSC, together with other government agencies, have announced new industrial policies (such as the “5 plus 2 Industrial Innovation” and the “ Forward-looking Infrastructure Construction” projects) to encourage the investment in specific innovative industries including internet of things(IoT), smart machinery, green energy, biomedicine, defense technology, circular economy, new agriculture, and railway vehicles. Through government budget support, business opportunities with a total of USD 45.5 million is expected to be created, which has paved the way for the recruitment of foreign investment.

Taiwan government also provides certain incentives to attract investment, including the exemption of import duty, commodity tax, and business tax for investment in special zones (such as science industrial park, free trade zones, export processing zones, etc.), the 1-3 year deduction with annual rates of 10%-15% from business income tax for R&D expenditure of investment in specific industries. All of these industrial policies and investment incentives are not only the driving forces to attract foreign investments, but also act as rules of the game that shape the service ecosystem.

In order to create better investment environment and form relationships with other countries, Taiwan government has signed 7 free trade agreements, mainly with countries in central and south America and Asia. In this regard, due to special factors, Taiwan has faced certain difficulties in expending its outreach in signing FTAs, but within current constraint it still takes the best advantage of the relationship and resources of the existed signing counter parties and incorporate them as important partners and actors to the service ecosystem of the inward investment agency.

The focused actor, the inward investment agency, the ITSC, also provides complementary measures such as free services for investment plan consulting, assessment, and tax/legal/regulatory consultation, response to questions within 24 hours, match-making service for lands and spaces, etc., to attract other actors to participate and contribute more in the ecosystem.

Since Taiwan has an advantage in ICT manufacturing and is using it as a base to develop IoT industries, it is found that internet of things technology is also applied to the platform of inward investment agency. For example, an Investment Situation Room which uses IoT technology to collect and analyze updated investment information and statistics from actors in the ecosystem was just established. It allows more actors to be willing to join and engage in the ecosystem by using cutting-edge new technologies.

1.2.3 Strategic Nets

In the ecosystem of Taiwan's inward investment agency, the ITSC uses the value proposition of helping companies to invest successfully in Taiwan to reduce uncertainty and attracts sympathy from other actors. It also developed up a standardized operation procedure for investment service which outlines how value will be created by the entire ecosystem to incentivize relevant actors. However, the other actors in the ecosystem, like foreign chambers of commerce, may time to time express their different requirements for the ecosystem, which also foster the ITSC to tackle the convergence of the diverse actors so that every actor can play a role in value co-creation in the ecosystem and to collaborate in an increasingly committed way.

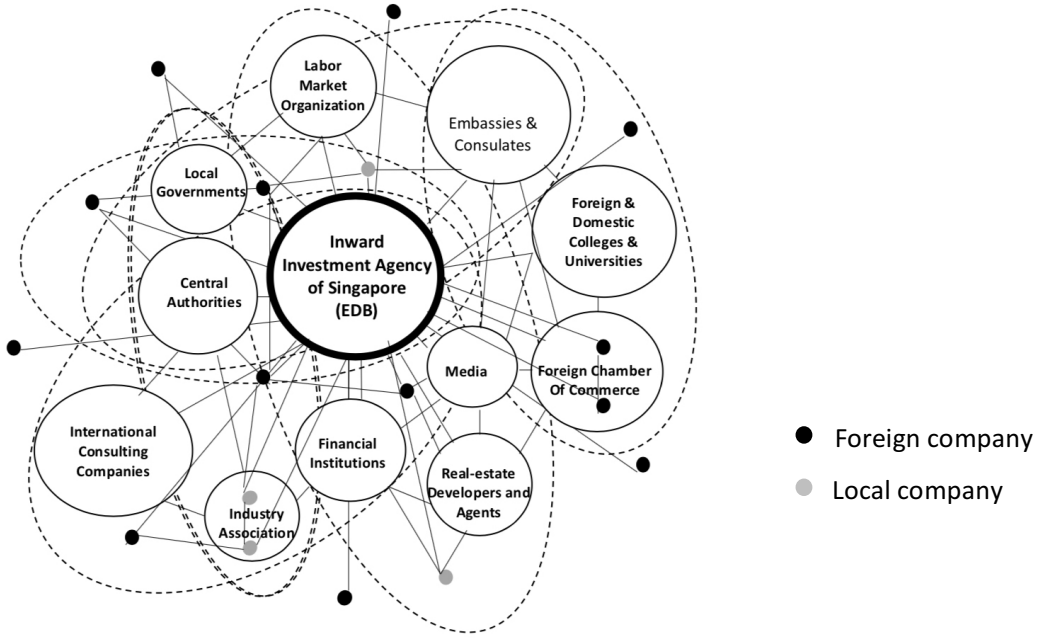
2. Singapore

2.1 Singapore's Inward Investment Agency- Economic Development Board (EDB)

The Singapore Economic Development Board (EDB), a government agency under the Ministry of Trade and Industry, is responsible for strategies that enhance Singapore's position as a global center for business, innovation, and talent. The EDB is selective in engaging and promoting investments which meet the resource profile and the aspirations of Singaporeans, with commitment to ensuring that activities in Singapore are fit for the future and sustainable in the medium to long term. Its core values are care, integrity, team, imagination, courage, excellence, nation (CITICEN). Shared by one and all at EDB, these core values shape and guide the organization in what it undertakes.

With deep insights and networks into Singapore's various industries, the EDB undertakes investment promotion and industry development in the manufacturing and internationally tradeable services sectors. Besides facilitating investments, it also engages Singapore's existing base of companies to transform their operations and boost productivity, and to generate growth in adjacent and disruptive areas by growing new businesses out of Singapore.

Figure 3: The Ecosystem of the Inward Investment Agency of Singapore



2.2 Investigation into the Service Ecosystem

2.2.1 Stakeholder Analysis

The EDB connects actors of industry associations, competent authorities, local governments, foreign and domestic leading enterprises, financial institutions, foreign and domestic chamber of commerce, Labor market organizations, media, Embassies and consulates, foreign and domestic colleges and universities, international consulting companies, to carry out the mission and tasks of the promotion of inward investment.

Within the service ecosystem, the main focused actor, the inward investment agency, the EDB, developed the value proposition of creating sustainable economic growth, with vibrant business and good job opportunities for Singapore, which attracts other actors to participate in the ecosystem.

2.2.2 Social Movement Mobilization

The EDB works with companies by providing information, connection to partners and access to government incentives for their investments, as well as their transformation and growth initiatives. It also works closely with other Singapore government agencies to constantly improve their pro-business environment, and ensure that industries are supported by a globally competitive workforce through talent development.

Singapore has signed 31 free trade agreements with countries around the world. In this regard, the EDB actively provides assistance in delivering explanations to its partners on the benefit a

company can gain from tariff deduction and the removal of non-tariff barriers through emails, conference, seminars, or calling on companies. It also provides formulas on its website to help companies calculate how much they can save from tariff deduction to attract more investments.

Singapore government provides the lowest corporate tax rates in Asia. A slew of financial incentives is offered to investors ready to expand their businesses, covering areas from equipment and technology, to business development, R&D and intellectual property, headquarters management, and industry development. Resident companies also enjoy additional benefits including protection from double taxation, tax exemption on foreign-sourced income and tax exemption for new start-up companies. The Global Investor Program (GIP) also accords Singapore Permanent Residence status to investors with substantial business track record and successful entrepreneurial background who intend to drive their business and investment growth from Singapore. An integrated series of incentives and programs has been tailor-made to welcome companies to integrate into both the business community as well as local society. Those efforts have earned Singapore the reputation for being the world's easiest place to do business, as well as the most competitive Asian economy.

With deep insights and networks into Singapore's various industries, the EDB can help investors to assess the advantages of setting up in Singapore as well as to highlight critical regulations that may be relevant to investors' business. It can connect investors with a wider network of government agencies and EDB partners (private companies) who can assist with business incorporation, taxation, legal matters and financial service. New businesses in Singapore may leverage EDB's network of partners in the private sector, who provide a full range of business support services.

2.2.3 Strategic Nets

The value proposition of the EDB is to creating sustainable economic growth, with vibrant business and good job opportunities for Singapore, which provides a broad vision for its partners (also the actors in the ecosystem) to participate in the related activities of the recruitment of foreign investments. With the vision, the country also creates an open platform allowing more partners/actors around the world to be part of the ecosystem with lower boundary limitations. Therefore, all kinds of actors or cluster of actors can express their feedbacks to the ecosystem with similar or opposite thinking and collaboratively co-create the value of the ecosystem.

3. Korea

3.1 Korea's Inward Investment Agency- Invest KOREA, KOTRA

Invest KOREA(IK), composed of Korea Trade-Investment Promotion Agency(KOTRA) employees, specialists and seconded officials from government ministries and agencies, is a Korean investment promotion organization established since 2003 to provide customized services support for the entry and establishment of foreign businesses in Korea. It works closely with its network of 42 overseas branches, known as Korea Business Centers, to provide comprehensive services for foreign businesses. It includes consultations, assistance with investment notification and corporate establishment, support for business activities in Korea and grievance resolution. It provides comprehensive one-stop services to foreign-invested companies to help them develop into global companies.

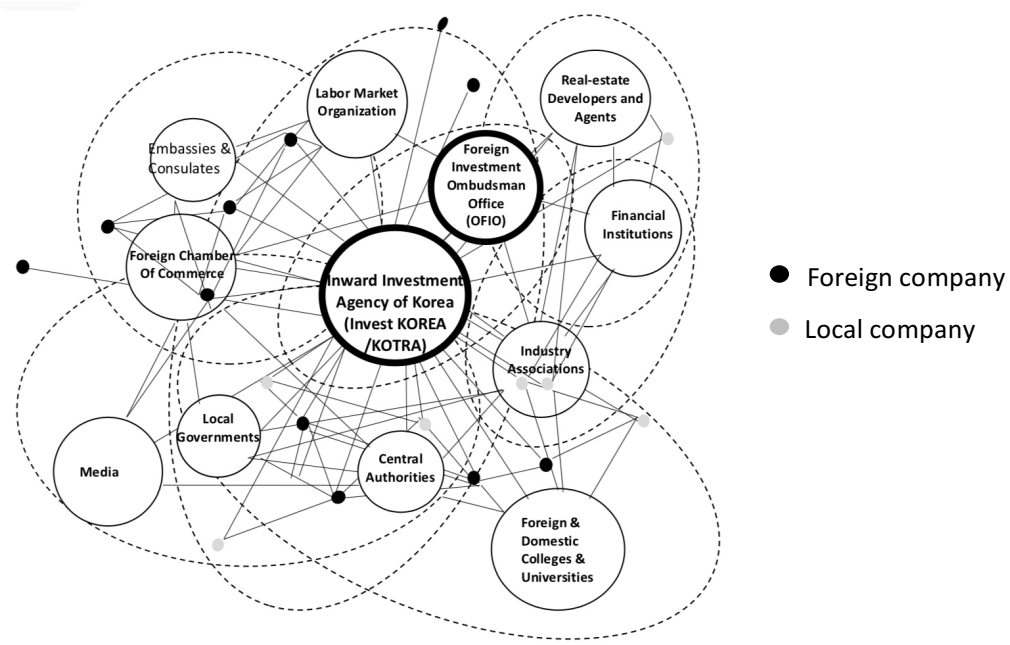
3.2 Investigation into the Service Ecosystem

3.2.1 Stakeholder Analysis

The Invest KOREA connects actors of Foreign Investment Ombudsman Office(OFIO), industry associations, competent authorities, local governments, foreign and domestic leading enterprises, financial institutions, foreign and domestic chamber of commerce, Labor market organizations, media, Embassies and consulates, foreign and domestic colleges and universities, international consulting companies, to carry out the mission and tasks of the promotion of inward investment.

The Value proposition of Invest KOREA is to contribute to the wellbeing of the Korean people and the development of human race by facilitating global business.

Figure 4 : The Ecosystem of the Inward Investment Agency of Korea



3.2.2 Social Movement Mobilization

In order to make the leap to a more attractive investment destination, Korea government is devoted to improving industrial structure by developing key industries, fostering convergence-based new industries, and nurturing high value-added service industries. It also endeavored to reduce economic uncertainty by Increasing flexibility of the labor market and developing the financial market.

Korea has signed 15 free trade agreements with countries around the world and is the first country in the world to complete the all FTAs signature with of the U.S, E.U., ASEAN, and China, with the FTAs effect to cover 49 countries.

The Invest KOREA carries out various activities to attract foreign investment, including finding potential investors, supporting investment projects, providing after care services and building cooperation with related agencies. Invest Korea Plaza, the first international business incubation center in Korea, also offers business consultation, administration support, investment and efficient one-stop services to foreign investors.

The Invest KOREA also employs one office to back-up it investment promotion mission. The Office of the Foreign Investment Ombudsman (OFIO) provides aftercare services to resolve a variety of grievances faced by foreign-invested companies doing business in Korea. The Ombudsman makes recommendations to the government and other organizations to improve the investment environment on behalf of investors, thereby helping resolve their grievances. The Investment Aftercare Division offers “home doctors” (experts in foreign investment) to provide one-on-one services for clients and rapidly identify and resolve problems.

3.2.3 Strategic Nets

In the ecosystem of Korea’s inward investment agency uses the value proposition of contributing to the wellbeing of the Korean people and the development of human race by facilitating global business to attract the other actors in the ecosystem. In spite of providing one-on-one investment services, the Invest KOREA also employs the Office of the Foreign Investment Ombudsman (OFIO) to provide aftercare services. The OFIO makes recommendations to the government and other organizations to improve the investment environment on behalf of investors, thereby helping resolve their grievances.

With the OFIO acting as intermediate between investors and the inward investment agency, it is more convenient for actors to exchange views on how to make a better ecosystem and therefore more easy to co-create value.

4. Analysis

4.1 Stakeholder Analysis

Past Researches on inward investment promotion mostly were conducted from the perspective of traditional merchandise-dominant logic, such as place marketing (Kolter 2002). They tended to consider value creation as a concept of value chain from a one-way and linear thinking. This paper takes a modern perspective from service-dominant logic to review the service ecosystems of the inward investment agency of Taiwan, Singapore, and Korea. It is found that all of the ecosystems of the 3 countries not only contain the major actors pointed out by traditional research (such as industry associations, competent authorities, local governments, foreign and domestic leading enterprises, financial institutions, foreign and domestic chamber of commerce, Labor market organizations, media, Embassies and consulates), but even also involve a larger coverage of actors such as domestic colleges and universities and international consulting companies, and the resources behind them, making the networks more complicated ecosystems which are more coherent with the reality.

4.2 Social Movement Mobilization

According to the observation and comparison to the 3 cases of ecosystems of the inward investment agencies, from the perspective of mobilization, it is found that institution, relations, beneficiary incentives, and application of new technology are all critical driving forces in

mobilization of ecosystems.

(1) Institutions

The governments of the 3 countries all initiates highlighted industrial policies and investment incentives to foster the investment and development of innovative and strategic industries, which can be seen as rules of the games to shape communications and interactions among actors and to reach purposeful goals in the ecosystems. Government of Singapore even owns greater authority in providing Taylor-made investment incentive packages to fit the diverse needs of specific investors. This kind of flexibility also allow the process of institutionalization to be with more opportunities for deinstitutionalization and reinstitutionalization. It turns out to be helpful to value innovation and sustained mobilization in an ecosystem.

(2) Beneficiary Incentives

All of inward investment agencies in the 3 cases provides complimentary services as incentives to attract existed and new actors to involve in and contribute to the ecosystems. These complimentary services include Investment plan consulting, assessment, and tax/legal/regulatory consultation. Taiwan even provide more services as response to questions within 24 hours, match-making service for lands and spaces, while Singapore takes extra care of business transformation and long-term growth for investing companies, and Korea highlights aftercare investment services. All of the above turn out to become important driving forces for actor mobilization and coordination in the ecosystems.

(3) Relations

To provide an investment-friendly economic environment, a lot of countries have endeavored to sign multilateral, plurilateral, and bilateral free trade agreements (FTAs). Through the signing of FTAs, a country not only can get better trade terms especially in the deduction of tariff or non-tariff trade barriers which in the end contribute to investment, but also can outreach to the singing counter parties and utilize their resources from mutual relationship to make the service ecosystems of inward investment agencies more international and comprehensive.

In the multi-case study of this research, it is found that Singapore and Korea both have good outreach in signing FTAs, while Taiwan, due to specific reasons, has less accomplishments.

(4) Application of New Technology

From the multi-case study, it is found that all of the 3 inward investment agencies take different level advantages of new technology in providing their services. Each of the agencies basically has its own portal website providing thorough information to investors, and offer on-line consulting assistance. It allows investors and other actors to require services, communicate, and interact with lower costs in time and money, therefore drive them to participate more in the ecosystems.

Taiwan’s inward investment agency, the ITSC, recently has also established the Investment Situation Room and employed IoT technology in collecting investment data, statistics, and files from actors, including related departments and agencies of central authorities, local governments, and investing companies for Big Data Analysis and AI applications. Through the effect of new technology, actors are more easily steered and mobilized to commit to the ecosystem because of the cost-down and facilitation of the participation process.

4.3 Strategic Nets

All of the 3 cases showed that through creating open and communicable environments for the service ecosystems, the focused actor of inward investment agencies can use their value propositions to reduce uncertainty and attracts sympathy from other actors and also require feedbacks from various stakeholders in the ecosystems. The accumulation of different ideas, opinions, and feedback persistently constitutes the value co-creation of the ecosystems.

The methods the 3 inward investment agencies use to shape open and communicable environments for the ecosystems may differ, however all contribute to value co-creation. For example, Singapore proclaims its value proposition with clear core values of care, integrity, team, imagination, courage, excellence, nation (CITICEN), allowing all actors more actively connect to each other and share resources. Taiwan developed up a standardized operation procedure for investment service and welcome the other actors such as foreign chambers of commerce to express opposite opinions. Korea even hires the Office of the Foreign Investment Ombudsman (OFIO) to act an intermediate to enhance the exchange of view among actors. All of the above help the facilitation of value co-creation of ecosystems.

DISCUSSIONS AND IMPLICATION

Theoretical Implication

Past researches of service-dominant logic have mentioned actors, through services exchange in the process of resource integration, gradually form a service ecosystem under the arrangement and impact of institution (Vargo & Lusch 2017). However, how actors in a service ecosystem are appealed and how they are mobilized to participate in the interaction and resource integration have seldom been explored. This paper borrowed the research stream of mobilization, through linking with the theories of service-dominant logic and service ecosystems, to investigate how key actors were motivated by the inward investment agencies, and how the emergent systems were mobilized and coordinated, evolving towards mature service ecosystems.

In this research, evidences are found to point that the following 4 factors are critical driving forces in the mobilization of service ecosystems: 1) Institutions- acting as rules of the game in service ecosystems, institutions shape interaction of actors and generate agency which strengthen the mobilization of services ecosystems. 2) relations- the breadth and depth of the relations among the actors effects on sustained mobilization, and the broader and deeper the relations are, the easier to have sustained mobilization in service ecosystems. 3) beneficiary incentives- the providing of preferential measures and the flexibility in use are important attraction to actors when services ecosystem need to mobilize them. 4) application of new technology- through the effect of new technology, actors are more easily steered and mobilized to commit to the ecosystem because of the cost-down and facilitation of the participation process.

Managerial Implication

In recent years, as the rise of discussions on the theory of value co-creation, the conceptual thinking of ecosystem has also been highly emphasized theoretically and practically (that means it has not only been explored from the perspective of service-dominant logic). However, the participants of a service ecosystem (in other word, the stakeholders/actors) usually possess different goals and value thinking, and how to mobilize them to participate in collective

construction to create an agency which power and strengthen a service ecosystem to evolve toward a mature one becomes a very important issue. Therefore, mobilization is an essential tool for the management of service ecosystems.

The managerial contributes of this research are on the 2 aspects: 1) knowing the theoretical findings of the 4 critical driving factors influencing mobilization of service ecosystems is also helpful to the practice of the management of services ecosystems. 2) The findings on the comparison of stakeholders/actors, mobilization measures, and the ways of value co-creation of the 3 cases of ecosystems of inward investment agencies of Taiwan, Singapore, and Korea can serve as helpful reference for policymakers in decision making.

LIMITATION AND IMPLICATION FOR FUTURE STUDY

The lack of data on the performance of the 3 ecosystems of inward investment agencies in this paper constituted the limitations of research. Future studies can further explore the relation between Mobilization and performance of service ecosystems.

CONCLUSION

(Vargo & Lusch 2017) pointed out that to support service-dominant logic theory of the market requires developing more midrange theoretical frameworks and concepts. These midrange theories can be partially informed by theories outside of marketing, including those under the rubrics of practice, evolutionary, complexity, ecological and structuration theories. Evidence-based research is also needed. To bridge the gap in the research of service-dominant logic, this paper borrowed the research stream of mobilization, through linking with the theories of service-dominant logic and service ecosystems, to investigate how key actors were motivated by the inward investment agencies, and how the emergent systems were mobilized and coordinated, evolving towards mature service ecosystems.

In Summary, this evidence-based research reached the finds that institutions, relations, beneficiary incentives, and the application of new technology are 4 critical driving factors in mobilization of service ecosystems. These findings may serve as midrange theoretical frameworks and concepts to the theory of service-dominant logic and pave ways for it toward a more comprehensive theory of the market. Additionally, mobilization is an essential tool for the management of service ecosystems. The findings on the comparison in actors, mobilization, and value co-creation of the 3 cases of ecosystems of inward investment agencies of Taiwan, Singapore, and Korea can also serve as helpful reference for investment policymakers to make decisions more correctly and precisely.

ABSTRACT

The first tool of knowledge chemistry was the knowledge spectrum describing the knowledge component of the knowledge-information-data hierarchy. The knowledge spectrum provides much information about knowledge describing the knowledge types which interact to permit intelligent behavior. Based the relationship between insight and Dretske's three knowledge types, a conceptual framework for the development of the force equations is used to create the force equations. The cognitive force calculated by the force equations are compared to the force which is obtained through moment models, and the force equations are refined as the graphic and mathematical techniques for determining cognitive force.

KEYWORDS: Knowledge Creation, Knowledge Management, Knowledge Chemistry

INTRODUCTION

Like chemistry's table of elements, the knowledge spectrum organizes information about knowledge and supports the decomposition of intelligent behavior into its cognitive elements. Building on the knowledge combustion analogy, the knowledge spectrum places seven knowledge types on a continuum and helps to explain the relationship between information, pragmatic knowledge, and semantic knowledge.

Randles, Blades, and Fadlalla (2012) stated that based on its spectrum location, a knowledge type's cognitive force could be determined. Furthermore, they stated that cognitive force was approximated by the shape of the semantic wall in Figure 1. These equations will provide a short-hand method for determining the cognitive force which is generated by the six pragmatic knowledge types: declarative, rules, triggering causes, maps, technical knowledge, and structuring causes. In this book chapter, the knowledge spectrum is reviewed, a deeper look at the knowledge spectrum is provided, and a conceptual framework for the development of the force equations is provided.

Development of a measure of cognitive force began with an attempt to understand increases in diagnostic confidence obtained from telemedicine consultations between specialists and physicians. Knowledge requirements, knowledge gaps, and diagnostic confidence were studied. The cornerstone of this telemedicine research was Dretske's (1988) definition of knowledge which described three knowledge types that control intelligent behavior. The knowledge requirements of the medical diagnostic process were described, and physicians' diagnostic confidence was inversely related to the size of their knowledge gap. Furthermore, the processing of diagnostic information and the provision of explanations by the specialist were found to increase the physician's diagnostic confidence.

Subsequently, the vacuum formed in the cylinder of the combustion engine was related to a knowledge gap. The knowledge combustion and vehicle analogy and the knowledge chemistry approach were developed, and an appreciation of knowledge's moderation and balance was gained. The knowledge spectrum in Figure 1 shows that external information passes through a window into the mind. Ushered through the window by a small number of sensory devices, this external information becomes declarative knowledge. Semantic knowledge is internal. According to the knowledge spectrum, this semantic knowledge is linked to the external environment through six pragmatic knowledge types: declarative, rules, signals, maps, technical skills, and structuring causes. These pragmatic knowledge types generate cognitive force while semantic knowledge generates no force. Instead, its contribution to cognitive force is attributed to the pragmatic knowledge types it serves. Furthermore, individually, a pragmatic knowledge type cannot generate cognitive force. They only have a potential force. Even the simplest knowledge types, rules and signals, must have small amounts of declarative knowledge embedded in them. The knowledge types of the knowledge spectrum must interact to generate cognitive force, and the objective of the knowledge chemistry approach is to study theses interactions.

The tools of knowledge micro analysis should enable organizations to optimize their use of knowledge resources by modelling their business processes using moment models. According to the composition property of knowledge, the knowledge spectrum's higher order knowledge types are composed of lower order ones. For example, a map is composed of declarative knowledge, rules, and signals. Seven components of cognitive force have been described. These components can be graphically portrayed using a moment model, which is the base element of an emerging modelling methodology.

Each knowledge type has a potential cognitive force that is released through interaction with other simple knowledge types. Describing the characteristics of the pragmatic knowledge types requires decomposing the interactions that occur to achieve a specific form of insight or knowledge combustion. This is made easier by Randles and Thachenkary (2002) who described the relationship between insight and Dretske's three knowledge types, and each

knowledge type is viewed as a means to an end. Based on the aforementioned research a conceptual framework for the development of the force equations is provided.

BACKGROUND

Beginning with a telemedicine study in the 1990s, this research has led to a deeper understanding of knowledge and yielded the knowledge chemistry approach, the knowledge spectrum, and the notion of cognitive force. This research supports the provision of a conceptual framework for the cognitive force equations and is provided to support the reader's understanding of this framework which will be developed in the near future.

Pragmatics

The role of pragmatic knowledge is to interpret information in a particular context and to relate it to events and action (Stamper, 1973; Penzias, 1989). According to Randles and Fadlalla (2004), Dretske's definition of knowledge provides a better understanding of the pragmatic process. Dretske (1988) stated that behavior is a causal chain governed by three types of knowledge. The first of these knowledge types is the triggering cause which is a summary form of knowledge that signals the presence of an external event. The second knowledge type is the structuring cause which explains the relation between the signal (triggering cause) and the external event. The third knowledge type is described as a map attached to a belief that guides one's actions (Dretske, 1988).

Determining how telemedicine impacted the fulfillment of medical diagnostic knowledge requirements and influenced diagnostic confidence was the focus of telemedicine research by Randles and Thachenkary (2002). An analysis of knowledge requirements, knowledge gaps, and diagnostic confidence was undertaken. In 1977 Conrath et al. proposed that changes in diagnostic confidence would correspond to bandwidth with higher bandwidth resulting in greater increases in diagnostic confidence. However, both phone supported teleconsultations and teleconsultations supported by audio and video communication technologies had similar influences on diagnostic confidence. Rather than an information/telecommunications perspective, Randles and Thachenkary (2002) took a cognitive one. They found that physicians' diagnostic confidence was based on their ability to fulfill knowledge requirements. Diagnostic confidence was inversely related to the size of the knowledge gap and the successful processing of information and provision of explanations was found to increase diagnostic confidence.

The telemedicine research of Randles and Thachenkary (2002) described the relationship between insight and Dretske's three knowledge types. This research was extended through the knowledge combustion and vehicle analogy of Randles and Fadlalla (2004). Their knowledge combustion specifications described how a number of different knowledge types interacted to permit intelligent action introducing the knowledge chemistry approach and cognitive force.

In describing the knowledge combustion analogy, Randles and Fadlalla stated that pragmatics formed one part of the knowledge combustion equation providing the perspective from the engine. Their first proposition of knowledge chemistry was based on Dretske's (1988) three knowledge types and Sternberg's (1987) forms of insight. Their second proposition of knowledge chemistry stated that there are three primary forms of knowledge combustion, or insight, required for intelligent behavior. Their third proposition extended the second one,

proposing the existence of a fourth form of knowledge combustion (formulation), a planning process that is guided by the insight attained in a previous stage.

To describe what occurs between insight and action, the view from the vehicle was adopted. For the **vehicle analogy,** the vehicle embodies action, and there are devices that are engaged when the engine performs such as the tachometer, which indicates when to shift gears, and the speedometer that measures the speed of the vehicle. Knowledge combustion requires similar devices. According to the **knowledge combustion analogy**, action is controlled by two sets of cognitive processes that precede two emotions concerning knowledge and risk, to establish an **action threshold.** Although these control mechanisms do not contribute any force, in concert, they regulate action (Randles and Fadlalla, 2004). For example, after the problem is framed, a map is formulated. Simultaneously, at a deeper level, there is a subjective assessment of the map's adequacy as well as an assessment of one's ability to follow the map (diagnostic confidence). The second emotion emerges when the map is complete, and the next move is recognized. At this juncture, the consequences of the action are known, and a threshold is established. Only when diagnostic confidence is above the action threshold will an action be performed.

Knowledge Micro Analysis

Knowledge micro analysis focuses on the knowledge interactions that occur **in a moment's time**, in order to show how cognitive force is generated (Randles, Polin, and Abney, 2018). The links between the various knowledge types are analyzed, and these links represent seven components of cognitive force. The first three components: cohesion, coherence, and synergy form a summary measure. The other four components: complement, initiate, promote, and strengthen provide detail and permit a more in-depth description of how cognitive force is generated.

The work of Randles, Polin, and Abney (2018) extends the knowledge chemistry approach providing several propositions of knowledge micro analysis with micro propositions 1, 2, and 3 explaining why knowledge interacts and micro proposition 4 establishing three prerequisites for the generation of cognitive force. Micro proposition 1 is most relevant to this paper and is as follows: each knowledge type only possesses a potential force. Different knowledge types must interact to generate cognitive force.

A moment model is created through the development of a series of panels which depict the knowledge interactions that occur over several minutes of time. Just as data flow and activity diagrams support efforts to improve information flow within an enterprise; the graphical and mathematical techniques of knowledge micro analysis should provide organizations with a closer look at their critical knowledge intensive business processes (Randles, Polin, and Miller, 2019).

THE KNOWLEDGE SPECTRUM AND A MEASURE OF COGNITIVE FORCE

The first tool of knowledge chemistry was the knowledge spectrum which described the knowledge component of the knowledge-information-data hierarchy. As depicted in Figure 1, six knowledge types were placed on an explicit-to-tacit continuum. Randles, Blades, and Fadlalla (2012) stated that based on its spectrum location, a knowledge type's cognitive force could be determined. Furthermore, they stated that cognitive force was approximated by the

shape of the semantic wall in Figure 1. In this paper, a conceptual framework for the development of the force equations is provided. These equations will provide a short-hand method for determining the cognitive force which is generated by the six pragmatic knowledge types: declarative, rules, triggering causes, maps, technical knowledge, and structuring causes.

Knowledge Spectrum

Like chemistry's table of elements, the knowledge spectrum organizes large amounts of information about knowledge and supports the decomposition of intelligent behavior into its cognitive elements. Building on the knowledge combustion analogy, the knowledge spectrum helps to explain the relation between information, pragmatic knowledge, and semantic knowledge. The knowledge chemistry approach is based on a belief that intelligent behavior requires that different knowledge types interact and that more complex knowledge types (technical knowledge, semantic knowledge, and structuring causes) subsume more primitive ones (rules, signals, and maps). The cornerstone of this research was Dretske's definition of knowledge, which described how three knowledge types control intelligent behavior (Dretske, 1988). While proponents of the reverse knowledge management model have stated that knowledge cannot be separated from its tacit meaning structure (Tuomi, 1999), only one of Dretske's three knowledge types is closely related to meaning. The other two can operate independent of the tacit meaning structure, providing additional support for the recursive model.

Such characteristics of knowledge as the semantic wall and the window into the mind were depicted in the knowledge spectrum. Most importantly, characteristics of the spectrum knowledge types were described, and summary descriptions of these knowledge types is now provided. Eysenck and Keane (1990) defined declarative knowledge as the knowledge of knowing that (such as knowing that a specific diagnostic procedure should be conducted). Because of its factual nature, it is similar to information, which is described as a flow of meaningful messages that have the ability to increase, restructure, or change knowledge (Machlup, 1983).

The cognitive component of tacit knowledge is represented by the notion of internal mental models (Polanyi, 1966), and many descriptions of these internal mental models appear in the literature. There are numerous descriptions of rule-based knowledge. For example, semiotics identifies a number of transformations in which stimuli are transformed, such as letters to words and words to sentences (Ramaprasad and Rai, 1996). In addition, Weick and Bougon (1986) stated that predictive and associative knowledge were a collection of rules for processing information, and Covington (1998) described pragmatic rules, as rules of knowing what to say when.

Dretske (1988) defined the triggering cause as a summary form of knowledge that signals the presence of an external event. These signals, alarms, or indicators represent another type of internal mental model. This knowledge type analyzes a large amount of information and determines which information is relevant or irrelevant in a particular situation. The aforementioned knowledge types are ordinarily found at the machine level (Spiegler, 2003). As depicted in Figure 1, this machine-like knowledge falls between declarative and technical knowledge on the knowledge spectrum.

Randles and Fadlalla's (2004) fuel specifications suggest that map-like knowledge is necessary to frame problems and test hypotheses. Each of these different forms of knowledge combustion

has a different role and each requires a different map. For example, framing provides context and narrows a problem. This requires a map that is similar to a globe of the earth and provides a broad perspective. Conversely, hypothesis testing is an iterative process that requires more detailed information. This information is provided through a number of sub-state maps that are more like city street maps than a globe of the earth. These sub-state maps provide procedures for determining which path to take from a specific problem sub-state and provide specific directions like the ones provided in a cookbook.

Knowledge has a technical component which is the knowledge of how to do something (Nonaka, 1994) and is also referred to as procedural knowledge (Fetzer and Almeder, 1993). Technical knowledge resides in the mind and the body (Polanyi, 1966), and is placed in the middle of the knowledge spectrum establishing a broad boundary between tacit and explicit knowledge types. In describing the "new management science," Herbert Simon (1985) understood that the coordinated use of only a small set of simple motor skills became a complex mental task. While simple cognitive tasks require little coordination and limited semantics, more complex tasks require greater coordination and/or semantics. Figure 1 shows that there are different types of technical knowledge which vary with respect to whether they reside more in the body or the mind.

Semantic knowledge attaches meaning to data to create information (Ramaprasad and Rai, 1996). The subsidiary component of semantic knowledge processes cues captured by one's sensory devices and invokes a specific part of the meaning structure (Polanyi, 1998). Meaning representations are described as a background. This background is a tacit knowledge type, and the way these meaning representations are created and maintained is not well understood (Prosch, 1986). As shown in Figure 1, this background knowledge is represented by the semantic wall and semantic knowledge is most prominent in the upper bound on the knowledge spectrum where it is closely related to the structuring cause.

Dretske (1988) stated that the structuring cause was the most important knowledge type, and, as depicted in figure 1, the structuring cause is the most tacit knowledge type. The structuring cause is a deep network of facts, and many of its connections are hidden deep inside the structure. The role of the structuring cause is to generate an explanation that motivates action. This requires the identification of relevant strings of thought that may seem unrelated (on the surface) but are connected at a deeper level.

A Deeper Look at the Knowledge Spectrum

The knowledge spectrum illustrates that simple knowledge types have a dual role with one being internal and semantic and the other being external and pragmatic. As depicted in Figure 1, information passes through a window into the mind and is inspected by myriad triggering causes. These triggering causes signal the occurrences of external events and initiate rules that invoke maps to guide subsequent actions. These simple knowledge types also interact with the internal, semantic processes delivering peripheral data for processing. The semantic processes reciprocate this sharing of external information by activating specific parts of the meaning structure so a map can be formulated. The continual, intermittent interaction between the pragmatic and the semantic processes amplifies the declarative knowledge embedded in the rules and signals, enabling rules and signals to retain their message. Consequently, this embedded declarative knowledge can be located by the appropriate sensory input device.

Repetition and practice results in an intense interaction between pragmatic and semantic processes. When a new concept is established in the semantic wall, rules and signals are created to look for this specific incoming information. These distributed knowledge types transmit the peripheral information to specific parts of the semantic wall, giving knowledge an adhesive quality. This adhesive quality of knowledge allows additional knowledge to be obtained about myriad topics with little cognitive effort.

The dual role of rules and signals and the adhesive quality of knowledge illustrate the importance of balance and complement with respect to the interaction of different knowledge types and different forms of the same knowledge types. The knowledge combustion and vehicle analogy of Randles and Fadlalla (2004) revealed that each form of knowledge combustion uses seven knowledge types in a different way. For framing, the pre-semantic processes are intense while the semantic, pragmatic, and technical ones are simple. Alternately, the technical and pre-semantic knowledge requirements are minimal for formulation, while the semantic and pragmatic requirements are moderately complex.

Through diversity of form and function, knowledge is able to do myriad things using only four forms of knowledge combustion and seven knowledge types. The cognitive force of the each of the pragmatic knowledge types is based on their particular characteristics, and each knowledge type is viewed as a means to an end. Rules are the means to the selective comparison form of insight. The triggering cause is the means to the selective encoding form of insight, and the structuring cause is the means to the selective combination form. This relationship was first described by Randles and Thachenkary (2002), and by treating a knowledge type as a means to an end, a better description and understanding of these knowledge types can be attained.

After the creation of the knowledge spectrum, it became increasingly clear that even the simplest knowledge types (rules and signals) must have small amounts of declarative knowledge embedded in them. This embedded knowledge serves as a label or code, which is compared to incoming sensory data. According to the composition property of knowledge (Randles, Blades, and Fadlalla, 2012), the knowledge spectrum's higher order knowledge types are composed of lower order ones. For example, a map is composed of declarative knowledge, rules, and signals, and the aspect of technical knowledge that is in the mind (as opposed to the body) is composed of maps, rules, and signals.

With respect to cognitive force, knowledge must interact to generate cognitive force and each knowledge type only has a potential force. Furthermore, semantic knowledge is internal and generates no cognitive force. Instead, semantic knowledge is linked to action through the aforementioned five pragmatic knowledge types which interact with the external environment (the other side of the window) and generate cognitive force. Furthermore, the formulation form of knowledge combustion is based on the insight attained in a previous stage. It is a prelude to action and generates no cognitive force. Instead, the forces of the formulated maps are attributed to the processes they support. For example, in medical diagnosis the hypothesis testing stage subsumes the problem space map produced in the formulation stage.

To explain how cognitive force is generated, a study of the interaction of knowledge began, and moment models emerged as an approach for studying these interactions. Moment models depict the interactions between different knowledge types and between different forms of the same knowledge type providing an in depth look at seven components of cognitive force (Randles, Polin, and Abney, 2018). The ring links and base nodes presented in the static model

represent the cohesion, coherence, and synergy components of cognitive force. The static model also presents the links between similar knowledge type nodes (SKT links). The SKT links connect similar knowledge type forms to their base nodes and represent the complement component of cognitive force. The dynamic model presents the links between different knowledge type nodes (DKT links) over several minutes of time. These links represent the initiation, promotion and depth components of cognitive force.

Conceptual Framework for the Cognitive Force Equations

Knowledge is compact and neat and will often take the following course. The triggering cause will frame the situation and invoke a map. The requested map is formulated and is subsumed by hypothesis testing, serving as the basis of more detailed sub-state maps. These sub-state maps are formulated during hypothesis testing, which is an iterative, step-by-step process. The process moves from framing, to formulation, and then to hypothesis testing. It is first guided by simple, standard operating procedures. After the situation is framed, a map of a narrow piece of a vast problem space is formulated. Finally, sub-state maps are formulated, when needed, during hypothesis testing.

While maps provide guidance, it is technical knowledge that is most important during hypothesis testing. Technical knowledge permits the collection and interpretation of required information. However, these skills have little value until the collected (current) information is compared to an expected pattern of facts. Based on a small to moderate number of rules, the next action is determined.

Describing the characteristics of the pragmatic knowledge types (rules, signals, maps, technical knowledge, and structuring causes) requires decomposing the interactions that occur to achieve a specific form of insight or knowledge combustion. This is made easier by Randles and Thachenkary (2002) who described the relationship between insight and Dretske's three knowledge types, and each knowledge type is viewed as a means to an end.

As the basis of all intelligent action, there are many forms of rules performing myriad cognitive functions. A rule serves as a means to the selective comparison form of insight with current information being compared to an expected pattern of facts. It also relates to the hypothesis testing form of knowledge combustion which is an iterative, step-by-step process. In considering the cognitive force that rules generate, the number of rules that must be processed and the number of conditions that must be analyzed to achieve the aforementioned form of insight determines its cognitive force. However, underlying the pragmatic rules that guide action are pre-semantic rules that transform stimuli to letters, words, and sentences. Their force is minimal and is captured by the rules that guide action.

A rule's semantics must also be considered in determining the contribution of rules to cognitive force, as hypothesis testing is involved in a diverse range of activities. However, semantics' influence on a rule's cognitive force is minimal. Rules only possess a small amount of declarative knowledge and are a distributed knowledge type that exists separate from semantic knowledge. Rules are a simple, low energy knowledge type, and a factor of 3 (low, moderate, or high) should suffice in calculating the semantic influence on a rule's cognitive force. Consequently, for rules, cognitive force is a function of the number of rules and conditions that must be processed and analyzed with the sum of these numbers multiplied by a semantic factor of 1, 2, or 3.

The triggering cause rapidly analyzes a stream of external information to identify its salient part. It serves as a means to the selective encoding form of insight which requires distinguishing between relevant and irrelevant information. Like a rule, a signal is a distributed knowledge type that exists separate from semantic knowledge. Because of its dual role as liaison between external and internal processes, the signal is also self-sustaining. The map that guides framing is simple because framing relies on an analysis of readily available information. Standard operating procedures are followed, and the role of the structuring cause, which is to motivate action, is minimal.

The cognitive force that is generated by a triggering cause is determined by the number of variables that must be analyzed to achieve the selective encoding form of insight. The semantics of a signal must also be considered in determining a signal's force. However, like a rule, the influence of semantics on a signal's cognitive force is minimal because a signal only possesses a small amount of declarative knowledge. A factor of 2 (low or moderate) should suffice in calculating a signal's cognitive force. Hence, the cognitive force of a signal is a function of the number of variables that must be analyzed to achieve the selective encoding form of insight multiplied by a semantic factor of 1 or 2.

Intricate atlases of the world and elaborate production schedules are recorded maps, and creating these maps and schedules required great effort. They are valuable sources of information and are studied and learned by many intelligent agents, serving as the basis of their internal maps. However, the maps that are in the mind are small composed of a small number of rules and signals, each with a small amount of embedded declarative knowledge.

Hypothesis testing uses maps more extensively than any of the other three forms of knowledge combustion. The hypothesis testing task provides an excellent glimpse at the kinds of maps that guide intelligent action. Initially, an internal, problem space map composed primarily of triggering causes is provided. These triggering causes serve as beacons marking positions (sub-states) in a narrow problem space, and each of these beacons is identified by a specific pattern of facts. At each juncture of a problem space (a sub-state), there are several alternate branches, and each step of hypothesis testing requires a detailed sub-state map to determine which branch to take. The previously formulated narrow problem space map is subsumed by hypothesis testing. This narrow map of beacons and labels serves as the basis of the more detailed sub-state maps. These sub-state maps are only formulated when required and are primarily composed of a small number of rules that compare current information to an expected pattern of facts.

Because hypothesis testing is a step-by-step process, the breadth of these internal maps is narrow. For example, a map composed of 7 rules and 7 signals, each with a label of 25 characters would require the recall of 2 pages of information. For a label of 50 characters, 4 pages would be required, and the ability to recall maps that are ten to twenty pages in length with 30 rules and 30 signals seems realistic. However, this would require many years of study and practice.

Except for rules and signals, maps are devoid of other knowledge types. The formulation of a map delays action, and the role of the structuring cause (to motivate action) is not significant. Composed of only a small number of signals and rules, their cognitive force is approximately the sum of the forces of seven rules and seven signals. Furthermore, the number of conditions for the seven rules is either: small (2), medium (4), or large (6). The number of variables required

to identify a location in a problem space is either: small (5 or less), medium (6 to 10), or large (greater than 10 and less than 20).

Only if a map is novel and complex would the structuring cause have a significant role. In this case, an explanation would have to be developed to motivate the conduct of a novel action. Hence, the risk of the prescribed action is another variable influencing a map's complexity and force. To determine a map's cognitive force, the sum of the force of each of the rules and signals would be multiplied on a scale from 1 to 5 by a factor of: 1 for little risk and 5 for very risky actions.

Technical knowledge is the knowledge of how to do something and resides in the mind and body. According to Randles, Blades, and Fadlalla (2012), it is the level of control and semantics which determines what is low, moderate, or exceptional with respect to the intellectual (of the mind) aspect of a technical skill. With respect to technical skills that are more of the body, control is the key, and this requires maps. Through practice these maps are distributed to the body and performed with little thought. The internal map in the mind directs messages to the maps distributed in the body. In a thousandth of a second, these signals invoke physical actions that range from simple, mechanical operations to quite elaborate movements. However, these movements only occur if a small number of rules and signals, operating in the mind and body, interact in a millionth of a second. Finally, with respect to the body/mind dichotomy of technical knowledge, exceptional skill in one is usually coupled with less than exceptional skill in the other. This suggests that there is a cognitive limit with respect to the attainment of technical skills and reinforces how important practice is in the attainment of these skills.

With respect to technical skills of the mind, which is the focus of this research, the maps that guide action and the semantic richness of the endeavor are most important. As previously discussed, there are many types of internal maps that guide intelligent action, and the mind only works with several pages at a time. To reduce cognitive burden, even the most intellectual (of the mind) skills, distribute some of this how to knowledge to the body. For example, writers almost effortlessly type in their work as they wrestle for just the right word, and accountants use spreadsheet technology, without barely thinking, to solve the business problems they must attend.

It is the level of semantics that determines what is low, moderate, or exceptional with respect to the intellectual aspect of a technical skill. For example, it is the composer's rich semantics that distinguishes the composer from most musicians, and differences in semantic richness distinguish teachers from professors, bookkeepers from accountants, and nurses from doctors. To determine the cognitive force of a technical skill, the force of each of the maps that is utilized would be multiplied on a scale from 1 to 5 by a factor of: 1 for moderate semantic richness and 5 for extreme semantic richness, and these products would be summed. To factor in the force of the explanation which the structuring cause must generate to motivate action, the sum of the previous calculations would be multiplied by a risk factor on a scale from 1 to 5 (1 for little risk and 5 for extremely risky).

The knowledge requirements of the first three forms of knowledge combustion are moderate. But, this changes with the fourth form of knowledge combustion, which is depicted by the confirmation stage of medical diagnosis. Confirmation is introspective focusing on a few discordant facts. There is little need for a map to guide action. Confirmation is consumed with

thought, requiring recognition of the relationship between seemingly unrelated things. Attaining this form of insight is dependent on the structuring cause.

By identifying relevant facts that may seem unrelated (on the surface) but are connected at a deeper level the structuring cause can generate profound insights. All professions have members who reach beyond the routine to obtain some novel, perhaps, grand insight (creative thinkers). This creativity and grand insight corresponds to the upper sectors of the knowledge spectrum and the beginning of the structuring cause. Based on the semantics of the discipline which is based on a scale of 1 to 3 (1 for difficult semantics, 2 for very difficult semantics, and 3 for extremely difficult semantics), the cognitive force of the structuring cause is the cognitive force of a high-level technical skill multiplied by its semantic factor.

Further along the knowledge spectrum, beyond these creative thinkers are the geniuses that have emerged in myriad arts and sciences such as Bacon (philosophy), Da Vinci (science), Wagner (music), Picasso (painting), Einstein (physics), and Hayek (economics). This creativity and genius corresponds to the upper sector of the structuring cause and is measured on a scale of 1 to 3 with 1 being lowest level genius and 3 highest level genius. The cognitive force of the structuring cause is the cognitive force of a high-level technical skill multiplied by a semantic factor and then multiplied by a genius factor.

FUTURE RESEARCH

Using the conceptual framework provided in this paper, the force equations will soon be developed. Using moment models, moderately complex technical skills will be studied. The cognitive force calculated by the force equations will be compared to the cognitive force which is obtained through a moment model which depicts the interactions between different knowledges. The force equations will be refined as the graphic and mathematical techniques for determining cognitive force are calibrated. These techniques should enable organizations to determine the cognitive force which is generated by their knowledge intense business processes and knowledge-based technologies. Then the relationship between cognitive force and organization success will be studied.

ABSTRACT

This research develops a model for characterizing the relationship of risk management practices with counterfeit prevention efforts and supply chain (SC) performance. A structural equation model is proposed that examines the relationships among SC counterfeit mitigation (CM), SC risk management integration (RMI), firm SC cost performance (CP) and service performance (SP), and overall firm performance (FP). Based on the participation of over 100 managers, greater maturity in CM appears to be associated with greater RMI, while greater RMI is associated with better CP and SP. Better SC performance is, in turn, associated with improved overall FP. Our findings suggest that RMI fully mediates the relationship between CM and SC performance.

KEYWORDS: counterfeiting, supply chain integration, risk mitigation, firm performance

INTRODUCTION

Counterfeiting is a serious issue for supply chain managers as they experience challenges in preventing inferior products from impacting their organizations and from reaching customers (D'Amato and Papadimitriou, 2013). It has the potential to disrupt the operations of suppliers, manufacturers, and downstream stakeholders in the SC. Therefore, the supply chain represents an important nexus for counterfeit research because of the effect counterfeiting disruptions have on SC cost, profitability and the ability to meet service expectations (Zhang and Zhang, 2015; Jeong, et al., 2012). However, empirical research on SC efforts to mitigate the effects of counterfeit infiltration, and the impact on firm performance is very limited.

Many organizations have developed approaches for avoiding or mitigating risk, including counterfeit risk. However, only recently has there been movement toward a standard for supply

chain risk management. The ISO 9001:2015 standard, for example, requires certified organizations to demonstrate risk-based thinking (Kymal and Reid, 2015).

While global interest in quality programs such as TQM and ISO 9001 has been increasing for some time, there are many recent notable examples of the increasing incidence of counterfeiting penetrations into supply chains that impact on quality and the bottom line. Therefore, standards such as ISO 9001:2015, with its focus on risk management, have the potential to be a standard for the active management of both supply chain quality and risk. The present study examines if superior risk-based thinking, such as is required in the latest ISO 9001 standard, is associated with positive performance outcomes in US supply chains. Therefore, this research adds to the literature by exploring the value of risk management integration in mitigating supply chain risk in general, and counterfeit risk in particular.

Next, we provide background on supply chain risk, counterfeiting, and related supply chain performance. We then develop our model and propose a set of hypotheses, explain the study methodology, and present our findings. We conclude by offering theoretical and managerial implications for scholars and supply chain managers.

LITERATURE REVIEW

Interest in the impact and mitigation of risk in the supply chain has recently experienced significant growth in the research literature. There has been a pronounced and sustained rise in the number of articles on the subject (Ho et al., 2015). Classifications of supply chain risks among researchers have included: controllable and uncontrollable risks, environmental risks, financial, information, intellectual property, and reputation risks, process and technology risks, logistics, supply and demand risks (Punniyamoorthy et al., 2013; Samvedi et al., 2013; Zhao et al., 2013; Wildgoose et al., 2012; Tang and Musa, 2011; Blackhurst et al., 2008; Tang and Tomlin, 2008; Wu et al., 2006; Chopra and Sodhi, 2004; Harland et al., 2003).

Counterfeiting, as a supply chain risk, can occur in a variety of ways. D'Amato and Papadimitriou (2013) characterize counterfeiting by the LISC (legitimate-illegitimate supply chain) model that describes interaction between legitimate and illegitimate supply chains. Their study of counterfeiting in the luxury industry identifies six types of supply chain risk related to counterfeiting. These include: pure counterfeiting (demand for counterfeit goods fulfilled with counterfeits from an illegitimate retailer), infiltration (demand for original goods fulfilled with counterfeit by a legitimate retailer), product diversion (demand for counterfeit goods fulfilled with legitimate goods from an illegitimate retailer), factory overrun (extra product sold by a legitimate or illegitimate retailer), retail service copycatting (demand for original goods fulfilled by an illegitimate retailer but known to the legitimate customer with varying product types), and shoplifting (demand for original goods fulfilled through theft at a legitimate retailer with varying product types and then resold). Berman (2008) classifies counterfeits into four groups, including: copies that look like the authentic product and consumers know they are buying fakes; third-shift products, made by suppliers outside of the legitimate contract, and sold under the brand name; non-conforming product that is intentionally identified as such and sold through regular channels; and reverse-engineered products that pose deceptively as authentic.

The costs associated with counterfeiting are substantial. It has been estimated that counterfeiting costs companies anywhere from 10-20% of sales (Shultz and Saporito 1996). The formation of the World Trade Organization (WTO) was a significant step toward better regulation

of counterfeiting related to intellectual property theft through the Uruguay Round strengthening of the General Agreement on Tariffs and Trade. However, there have been problems with enforcement and some economies still waiver on the agreement. For example, even though China joined the WTO in 2001, its share of counterfeits has continued to be much greater than that of any other US trading partner (Krause 2006).

It is clear from the literature that counterfeiting is a complex risk that can present in different ways and is very costly to the supply chain when it occurs. Therefore, effective mitigation of such risks is critical to the bottom line. The simplest generic approach for risk management described in the literature involves several steps, including: identification of potential risks, estimating their likelihood of occurrence, assessing the severity of impact on the supply chain should they do occur, engaging a real-time response when the risk event occurs, and then monitoring the effectiveness of the mitigation action (Ho et al. 2015; Kouvelis et al., 2011). A mature risk management process is characterized by organizational actions taken to avoid the occurrence of a risk event and effective mitigation of risk events that are difficult to avoid, so as to minimize the negative impact on supply chain service and cost. In relation to this, researchers have proposed effective ways to detect and reduce counterfeiting activity. Bush et al. (1989) proposed actions such as adding unique identifiers to products, informing the public about counterfeit risks, rewarding forward channel members for detecting and rejecting counterfeits, and monitoring channel distribution. Shultz and Saporito (1996) suggest co-opting offenders by purchasing them, educating stakeholders in transition economies, doing a better job marketing the brand, improving international surveillance, using high-tech labeling, and evolving the product more quickly. Berman (2008) recommends educating customers, using authentication technology, exercising better control of outsourced supply, monitoring websites, and taking legal action. Hoecht and Trott (2014) identified ten general anti-counterfeiting strategies from the risk literature. These strategies included: co-opting offenders, industry coalitions, internal/external guanxi, educating in-company decision-makers, raising awareness with advertising, surveillance, high-tech labeling, product/process innovation, legal enforcement of legislation, and withdrawal from high-risk markets.

The literature reports that organizational structure and characteristics may also contribute to risk management success. Organizations characterized by agility and flexibility, in addition to systematic contingency planning, are better able to manage risks in general (Ghadge 2012). A total quality management (TQM) culture has been associated in the literature with innovative, change-oriented and adhocratic organizations (Dellana and Hauser, 2000**).** These organizations have an external orientation on the well-being of the organization and a structure of flexibility and change, that may contribute, by extension, to more successful management of supply chain risk. Florio (2017) found that TQM practice is positively associated with risk management maturity. ISO 9001 certification, a standard for meeting quality management system requirements, incorporates the principles of TQM into its certification criteria. Thus, one would expect TQM principles and practices to be present in organizations that have achieved ISO 9001 certification. Hence, ISO 9001 certification may be able to signal risk management capabilities because of the attention the standard brings to improving process management through the principles of TQM. This is particularly true for the latest iteration of the standard, ISO 9001:2015. The 2015 version of the ISO 9001 standard explicitly incorporates risk management in the quality management system to overcome this weakness in the prior standards. This new emphasis on risk-based thinking recognizes that disruptions due to realized risk events impact negatively on customer satisfaction and must be proactively managed.

In the literature we find that firms can be better prepared to manage supply chain disruption by reducing the complexity of supply chain interactions and by becoming more agile and flexible by adopting a culture of innovation, (Ghadge et al., 2012; Scholten et al., 2014). But it is more efficient for supply chain members to proactively avoid such risks in an integrated fashion (Ho et al., 2015). As previously noted, organizations with more mature process monitoring and improvement practices appear to also have more mature risk management programs (Florio, 2017). Risk management maturity is also associated with better integration of supply chain members because it facilitates more rapid identification and better mitigation of risk events. Zhao et al. (2013) report that supply chain integration is an important driver for schedule attainment, competitive performance, and customer satisfaction; supply chain risks decreases as supply chain integration increases, (Zhao et al., 2013). By extension, organizations that exhibit a greater level of supply chain risk integration are likely to be more focused on risks in general, including counterfeit risk.

The occurrence of counterfeiting events in the supply chain increases uncertainty, which can logically result in decreased service performance and increased supply chain related costs. Organizations act in response to uncertainty by specializing and standardizing different tasks (Drazin and Van de Ven, 1985). Standardization improves consistency, providing superior visibility into inventory and service issues. Greater consistency results in lower supply chain costs and increased supply chain service performance (Li et al., 2005). According to Matthew and Mee (2008), as global markets grow increasingly more consistent (i.e., less variable and more efficient), competition occurs between entire value chains. Therefore, top managers seek to reduce costs and improve service performance so that the overall supply chain may gain competitive advantage. This is shown to result in improved overall firm performance (Chapman and Carter, 1990; Akinc, 1993; Agrawal and Nahmias, 1997; Frohlich and Westbrook, 2002).

One aspect that should be considered when comparing organizations in relation to risk management is organization size. Park *et al.* (2007) report that larger firms achieved quality certification compliance monitoring and measurement better than smaller firms. Lee and Palmer (1999) report that smaller organizations are more likely than larger ones to seek a quality certification due to external pressures. Further, larger firms appear to be better able to manage risk events than smaller firms (Kumar, 2011; Aguiar 2011; Skipper et al, 2010). Smaller firms lack the resources to develop a proactive approach, and instead are more apt to simply react to risk events after the fact (Ellegaard, 2008).

MODEL DEVELOPMENT

Counterfeit Mitigation and Risk Management Integration

Firms can be better prepared to absorb the shock of a supply chain disruption by engaging in better risk mitigation practices such as being more innovative or agile, reducing the complexity of supply chain interactions and creating modular/flexible processes, (Ghadge et al., 2012; Golgeci and Ponomarov, 2013; Gualandris and Kalchschmidt, 2013; Scholten et al., 2014). The level of firm's counterfeit mitigation is related to better integration of supply chain members allowing for quickly identifying risks.

As firms better mitigate risks (e.g., counterfeiting) supply chain risk decreases and supply chain integration increases (Zhao et al., 2013). In turn, it would be expected that a firm with enhanced

counterfeit mitigation would have increased risk management integration. Therefore, the following hypothesis is proposed.

H1a. SC counterfeit mitigation efforts positively contribute to SC risk management integration.

Counterfeit Mitigation and SC performance

Uncertainty underlies contingency theory (Venkatraman, 1989) and managers often pursue strategies to lessen the effects or mitigate events as a response to external uncertainty and competitive pressures (Fawcett et al., 2008). Contingency theory explains that managers must recognize the relationship of supply chain performance and their firm's internal structures to become, or remain, competitive (Luthans and Stewart, 1977). From a contingency perspective, managers attempt to eliminate the possibility of a risk occurring, shift the risk or outcome to a third party, and/or reduce the probability and impact of the risk by establishing mitigation strategies.

Such mitigation strategies or plans tend to take the form of avoidance (drop specific products), control (maintaining excess capacity, stockpiling), cooperation (joint efforts to improve supply chain visibility, sharing of risk information), and/or flexibility (multiple sourcing) (Juttner et al., 2003). Individually or used in combination with one another these strategies should improve areas of supply chain performance such as service and cost.

Contingency theory provides the foundation on which firms prepare for and minimize disruptions to their supply chains (i.e., supply chain risk mitigation strategies). In turn, increased efforts at supply chain counterfeit mitigation should have a direct and positive impact on supply chain service and cost performance. Therefore, the following hypotheses are proposed.

H1b. SC counterfeit mitigation efforts positively contribute to SC cost performance.

H1c. SC counterfeit mitigation efforts positively contribute to SC service performance.

The Role of Supply Chain Risk Management Integration as an Enabler of SC Performance

Counterfeiting within the supply chain brings with it higher levels of uncertainty and manifests itself in decreased service levels and increased costs to a firm experiencing it. From a contingency perspective, managers respond to uncertainty through improved risk management integration (Drazin and Van de Ven, 1985). Greater consistency enables supply chain benefits with lower costs and increased service levels (Li et al., 2005). Therefore, improved supply chain risk management integration is expected to lead to increased service and cost benefits. To this point, the following hypotheses are proposed.

H2a. Supply chain risk management integration positively contributes to firm supply chain cost performance.

H2b. Supply chain risk management integration positively contributes to firm supply chain service performance.

Service and Cost Performance as an Enabler of Overall Firm Performance

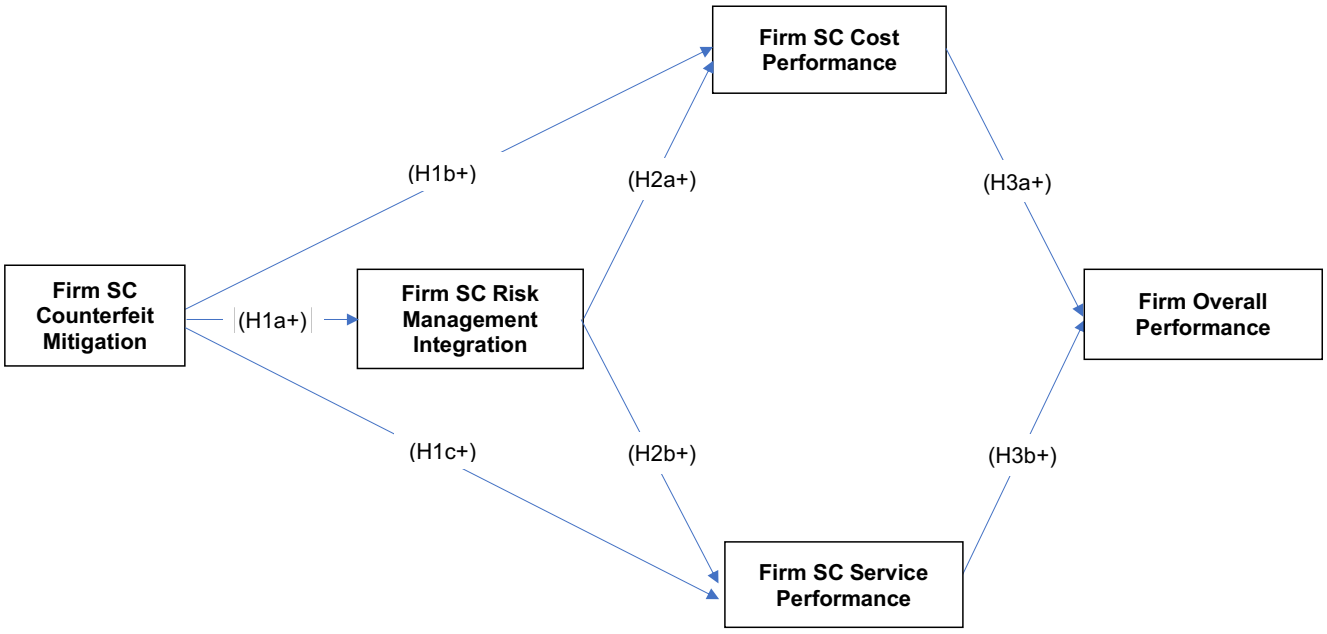
There are numerous studies that link supplier integration and improvements in supply chain cost and service to greater overall firm performance (Chapman and Carter, 1990; Akinc, 1993; Agrawal and Nahmias, 1997; Frohlich and Westbrook, 2002). Therefore, it is logical to posit that as a firm improves supply chain service and/or improves supply chain cost, overall firm performance would improve. From this the following hypotheses are developed.

H3a. Supply chain cost performance positively contributes to overall firm performance.

H3b. Supply chain service performance positively contributes to overall firm performance.

Figure 1 displays the proposed theoretical model. Size of organization (yearly revenues) is included in the model as a control variable.

Figure 1. Proposed theoretical model



METHODOLOGY

Construct Measures and Sample

This research employed an online survey to assess multiple constructs and empirically test a set of hypotheses. All measures were developed using items established in prior studies (Refer to Table II). Specifically, our counterfeiting mitigation measure was adapted from work by Ambulkar et al. (2015) on firm resilience and supply chain disruption. Our measure of risk management integration was developed based on prior work in the area of risk management maturity (Florio 2017). Both measures were completed using a seven-point Likert scale (1 strongly disagree to 7 strongly agree). In order to effectively assess three distinct areas of performance pertinent to our study, a series of previously validated items were used to measure firm SC cost performance, firm SC service performance, and overall firm performance (Chopra and Meindl, 2016; Claassen et al. 2008). All three of the performance measures were considered in relation to the firm's competitors and used a seven-point Likert scale (1 much worse - to 7 much better than competitors).

In an effort to further strengthen our survey instrument, a two-step process was followed to ensure content and face validity of the items and constructs being assessed (Dillman, 2000). In step one, the survey was sent to SC practitioners and experts for item review and feedback. In step two, we completed a pilot study to better assess the survey empirically. Both qualitative feedback and empirical data were collected during this process leading to minimal changes to the final survey.

Next, the survey was sent by email to a list of contacts provided by the Institute for Supply Management (ISM), the Council for Supply Chain Management Professionals (CSCMP), and the Association for Healthcare Resource and Materials Management (AHRMM). In all, the survey was sent to 1,741 SC professionals representing diverse organizations across multiple industries. This effort resulted in 140 completed questionnaires representing a response rate of 8%. Respondents included top-level managers (31.4%), mid-level managers (54.3%), and entry-level managers (12.1%). Participants' organizations were divided across two categories: manufacturing (36.4%) and services (62.9%). Finally, annual revenue was used as an indicator of organization size with small organizations having revenue less than $10 million (13.6%), mid-size organizations with revenue between $10 million and $1 billion (39.3%), and large organizations generating revenue in excess of $1 billion (40.7%). See Table I for a detailed breakdown of the survey participant demographics.

Table I. Survey Demographics

Respondent Job Title	**No.**
Top level manager	44
Mid-level manager	76
Entry level manager	17
Other	3
Total	**140**
Organization's Economic Sector	**No.**
Manufacturing	51
Services	88
n/a	1
Total	**140**
Organization's Yearly Revenue	**No.**
Less than 10 million	19
10 million to 1 billion	55
More than 1 billion	57
n/a	9
Total	**140**

Data Analysis

Descriptive statistics for all constructs and survey items are presented in Table II. Early versus late respondents were compared to evaluate non-response bias (Armstrong and Overton, 1977). The first and last quartiles of survey responses were tested for differences in construct means. The resulting p-values were 0.796 for the CM construct, 0.473 for RMI, 0.141 for CB, 0.177 for SP and 0.524 for the FP construct. The test results indicated that there were no significant differences between the mean construct responses obtained from the two groups across all five constructs, suggesting that non-response bias was not a threat to the integrity of the data.

Table II. Survey Scale Items Descriptive Statistics

Item/*Construct*		Mean	Std. Dev.
Supply Chain Counterfeit Mitigation (CM)		***4.285***	***1.718***
CM1.	We work to identify counterfeiting relationships with suppliers and/or customers.	4.471	2.051
CM2.	We have a person or team dedicated to identifying counterfeits in the supply chain.	3.942	2.224
CM3.	We have developed metrics to assess the risk of counterfeiting in the supply chain.	3.614	1.846
CM4.	After an occurrence of counterfeiting has been detected, it is analyzed thoroughly.	5.179	1.683
CM5.	We have an established counterfeit management process to follow in the event counterfeiting is detected.	4.207	2.082
Supply Chain Risk Management Integration (RMI)		***4.961***	***1.320***
RMI1.	We involve our suppliers in identification and mitigation of potential SC risks.	5.407	1.492
RMI2.	We encourage our suppliers to use a structured risk management process (e.g., ISO 31000).	4.252	1.776
RMI3.	We work with our customers to identify and mitigate potential SC risks.	5.216	1.586
Firm Supply Chain Cost Performance (CP)		***4.737***	***1.120***
	Compared to our major competitors:		
CP1.	Our total inventory cost is lower.	4.650	1.357
CP2.	Our stock-out cost is lower.	4.700	1.274
CP3.	Our emergency actions costs are lower.	4.836	1.228
CP4.	Our returns are lower.	4.743	1.238
CP5.	Our cash-to-cash cycle is shorter.	4.757	1.287
Firm Supply Chain Service Performance (SP)		***5.216***	***1.066***
	Compared to our major competitors:		
SP1.	Our information system is more responsive to our SC needs.	4.885	1.320
SP2.	Our financial transactions with SC partners run more smoothly.	5.007	1.168
SP3.	We have superior service flexibility.	5.400	1.314
SP4.	We are able to better meet our service-level agreements.	5.550	1.244
SP5.	Our SC is more visible.	5.245	1.362
Firm Overall Performance (FP)		***5.402***	***0.958***
	Compared to our major competitors:		
FP1.	Our profit margin is better.	5.080	1.192
FP2.	Our return on investment (ROI) is better.	5.080	1.273
FP3.	Our customer satisfaction is higher.	5.640	1.053
FP4.	Our quality is better.	5.790	1.182

Harman's single factor test was used to assess the potential for common method bias (CMB) (Podsakoff et al., 2003). A factor analysis was performed using all the different survey items included in the study to determine if most of the variance in the model was accounted for by one general factor. Since the percentage of variance explained by a single factor was less than 50 percent (the maximum percentage of variability explained by a single factor was equal to 43%), CMB was not deemed an issue.

The internal consistency, convergent validity and discriminant validity of the constructs as well as the reliability of the individual indicators were analyzed in order to assess the theoretical model. First, outer loadings were examined to evaluate the reliability of the survey items. Table III displays the outer loadings of the different items. The results of this portion of the analysis indicated an acceptable level of reliability for the different survey items since all indicators had loadings above the suggested cutoff of 0.70 (Hair et al., 2016).

Table III. Outer Loadings

Item	Outer Loading	*p*
CM1	0.871	< 0.001
CM2	0.875	< 0.001
CM3	0.876	< 0.001
CM4	0.786	< 0.001
CM5	0.902	< 0.001
RMI1	0.857	< 0.001
RMI2	0.737	< 0.001
RMI3	0.830	< 0.001
CP1	0.887	< 0.001
CP2	0.921	< 0.001
CP3	0.844	< 0.001
CP4	0.828	< 0.001
CP5	0.884	< 0.001
SP1	0.834	< 0.001
SP2	0.786	< 0.001
SP3	0.834	< 0.001
SP4	0.821	< 0.001
SP5	0.867	< 0.001
FP1	0.805	< 0.001
FP2	0.865	< 0.001
FP3	0.778	< 0.001
FP4	0.800	< 0.001

Cronbach's α, reliability coefficient ρ_A and composite reliability estimates were used to evaluate the internal consistency of the research constructs (Dijkstra and Henseler, 2015). All the different estimates were above the 0.70 cut-off recommended by Hair et al. (2016) (Refer to Table IV), suggesting adequate internal consistency across all five constructs. Convergent

validity was established using Average Variance Extracted (AVE) estimates. As shown in Table V, the AVE values were above the 0.50 cut-off recommended by Hair et al. (2016). The results indicate that all model constructs explained over half of the variance of their indicators, suggesting adequate convergent validity for the five research constructs.

Table IV. Construct reliability and validity

Construct	Cronbach's α	ρ_A	Composite Reliability	Average Variance Extracted (AVE)
CM	0.914	0.915	0.936	0.745
RMI	0.740	0.762	0.850	0.655
CP	0.922	0.928	0.941	0.763
SP	0.886	0.888	0.916	0.687
FP	0.829	0.836	0.886	0.661

Cross-loadings, the Fornell-Larcker criterion, and heterotrait-monotrait (HTMT) ratio of correlations approach were used to evaluate the discriminant validity of the model constructs. Cross-loadings were examined first. The loadings of some of the indicators on the different constructs were consistently high. For example, all the RMI1 and RM3 cross-loadings were greater than or equal to 0.40. Similarly, CP2, SP5 and FP2 had loadings at or above 0.60 on the three performance related constructs, confirming the fairly strong correlations among those constructs. While a few cross-loadings were relatively high, the loading on the hypothesized model construct was higher than the loadings on the remaining constructs for each individual indicator (Refer to Table V). Cross-loadings thus provide initial evidence for the constructs' discriminant validity (Hair et al., 2016).

Table V. Discriminant validity: Cross-loadings

	Construct				
Item	**CM**	**RMI**	**CP**	**SP**	**FP**
CM1	**0.871**	0.445	0.286	0.284	0.234
CM2	**0.875**	0.467	0.211	0.236	0.222
CM3	**0.876**	0.493	0.264	0.243	0.262
CM4	**0.786**	0.442	0.285	0.279	0.248
CM5	**0.902**	0.442	0.152	0.171	0.218
RMI1	0.430	**0.857**	0.465	0.437	0.504
RMI2	0.360	**0.737**	0.273	0.305	0.362
RMI3	0.490	**0.830**	0.433	0.432	0.509
CP1	0.224	0.453	**0.887**	0.608	0.592
CP2	0.317	0.463	**0.921**	0.688	0.637
CP3	0.152	0.332	**0.844**	0.597	0.513
CP4	0.255	0.422	**0.828**	0.619	0.546
CP5	0.269	0.471	**0.884**	0.630	0.573
SP1	0.350	0.488	0.573	**0.834**	0.621
SP2	0.083	0.402	0.570	**0.786**	0.617
SP3	0.210	0.368	0.621	**0.834**	0.569
SP4	0.207	0.327	0.572	**0.821**	0.573
SP5	0.315	0.433	0.649	**0.867**	0.605
FP1	0.270	0.453	0.656	0.537	**0.805**
FP2	0.219	0.497	0.668	0.613	**0.865**
FP3	0.186	0.444	0.376	0.600	**0.778**
FP4	0.220	0.475	0.398	0.604	**0.800**

Note: Primary loadings for each indicator are shown in bold.

To further analyze whether the constructs met the conditions for discriminant validity, the Fornell-Larcker method was used next (Fornell and Larcker, 1981). The square roots of the AVEs for each of the five model constructs was higher than the correlations of the construct with the other latent variables included in the theoretical model (Refer to Table VI), further suggesting that all constructs are valid measures of unique concepts.

Table VI. Discriminant validity: Fornell-Larcker criterion

Construct	**CM**	**RMI**	**CP**	**SP**	**FP**
CM	0.863				
RMI	0.532	0.810			
CP	0.283	0.494	0.873		
SP	0.285	0.491	0.720	0.829	
FP	0.276	0.575	0.658	0.722	0.813

Note: Square root of the AVE on diagonal in bold.

Finally, the HTMT ratio of correlations method was used to determine whether the HTMT values were lower than the suggested threshold of 0.85 (Henseler et al., 2015). As displayed in Table VII, for each combination of constructs none of the HTMT estimates were above 0.85, suggesting adequate discriminant validity across constructs (Henseler et al., 2015).

Table VII. Discriminant validity: Heterotrait-Monotrait (HTMT) criterion

Construct	CM	RMI	CP	SP
CM				
RMI	0.638			
CP	0.298	0.578		
SP	0.308	0.591	0.796	
FP	0.315	0.721	0.735	0.843

The model was also checked for collinearity problems. Variance Inflation Factor (VIF) values were calculated for all combinations of exogenous (or predictor) constructs (represented by the rows in Table VIII) and endogenous constructs (represented by the columns in Table VIII). Collinearity was not deemed an issue since all the resulting VIF estimates were below the threshold of five recommended by Hair et al. (2016).

Table VIII. Variance Inflation Factor (VIF) values

Construct	RMI	CP	SP	CM
CM	1.000	1.396	1.396	
RMI		1.396	1.396	
CP				2.081
SP				2.084

RESULTS

Hypotheses Testing

Next, the proposed structural equation model was tested. A summary of the test results is presented in Table IX. The research hypotheses were simultaneously tested in SmartPLS (Ringle et al., 2015). A bootstrap resampling method with 5,000 resamples was used to assess the level of significance of the standardized path coefficients estimated. Organization size, which was included as control variable in the model, was not significant at the 0.05 level (p-value of 0.223).

Table IX. Summary of hypotheses testing

Path		St. Weight	p	Conclusion
H1a:	CM → RMI	0.532	< 0.001	Supported
H1b:	CM → CP	0.027	0.778	Not Supported
H1c:	CM → SP	0.033	0.711	Not Supported
H2a:	RMI → CP	0.480	< 0.001	Supported
H2b:	RMI → SP	0.474	< 0.001	Supported
H3a:	CP → FP	0.282	0.002	Supported
H3b:	SP → FP	0.521	< 0.001	Supported

SC counterfeit mitigation was found to have a significant direct positive effect on SC risk management integration. The findings therefore provide support for H1a at the 0.001 level of significance. On the other hand, SC counterfeit mitigation was found to have an insignificant direct positive effect on both SC cost performance and SC service performance. Thus, H1b and H1c are not supported.

SC risk management integration was found to have a significant positive effect on both SC cost performance and SC service performance. The findings thus provide support for both H2a and H2b at the 0.001 level of significance.

With respect to firm overall performance, both SC cost performance and SC service performance were found to have a significant positive effect. H3a is therefore supported at the 0.01 level of significance, while H3b is supported at the 0.001 level of significance.

Mediation Analyses

The role of SC risk management integration in the link between SC counterfeit mitigation and SC performance was examined in more detail, based on the results of hypothesis H1b and H1c. Table X displays the results of the mediation analysis.

Table X. Summary of mediation analysis

Effect	Direct	Indirect	Total	VAF	Conclusion
CM → CP	0.027	0.256***	0.283**	90.46%	Full Mediation
CM → SP	0.033	0.252***	0.285**	88.42%	Full Mediation

Notes: ** p < 0.01, *** p < 0.001, VAF: Variance Accounted For

The mediation analysis results suggest that SC risk management integration fully mediates the relationship between SC counterfeit mitigation and SC performance. Variance Accounted For (VAF) values of 90% and 88% indicate that SC risk management integration explains most of the effect of SC counterfeit mitigation on both SC cost performance and SC service performance and, ultimately, on firm overall performance. The study findings therefore confirm the critical mediating role of SC risk management integration.

DISCUSSION, LIMITATIONS, AND FUTURE RESEARCH

Counterfeiting continues to be a complex issue facing supply chain managers tasked with preventing inferior products from impacting their organizations and reaching downstream channel partners and end users. A review of the literature reveals that counterfeiting is viewed as a significant risk that can impact the SC in different ways. For example, the proliferation of counterfeiting has the potential to disrupt the SC's of suppliers, manufacturers, and other stakeholders. Additionally, the occurrence of counterfeiting disruptions can have a substantial negative impact on SC cost, profitability and the ability to meet service expectations (Zhang and Zhang, 2015; Jeong, et al., 2012). As a result, the SC represents an important point of focus for counterfeit research and understanding how firms can mitigate this risk. Even still, empirical research on mitigating counterfeiting effects in the SC is quite limited. The current research aims to address this shortcoming in the literature.

Our study considers the role of risk management practices within counterfeit mitigation efforts and the subsequent impact on critical areas of SC performance. Specifically, a structural equation model that examines the relationships among SC counterfeit mitigation (CM), SC risk management integration (RMI), SC service performance, SC cost performance and overall firm performance was developed and empirically tested. Our findings indicate a higher level of CM is associated with greater RMI. Further, RMI appears to fully mediate the relationship between CM efforts and SC cost and service performance.

Our research makes the following contributions. First, interest in standards that incorporate risk-based thinking (such as ISO 9001:2015) is increasing as the importance of global supply chains grows. Therefore, this research contributes to the literature by exploring the value of risk management practices in mitigating supply chain risk in general and counterfeit risk in particular. Second, the literature has recently seen an increase in interest among scholars toward understanding the impact of risk and how to mitigate risk in the SC (Ho et al., 2015). Our study considers counterfeit mitigation efforts in relation to risk and therefore contributes to the extant literature on risk management in the SC.

Our study has a number of limitations to be addressed in future research. First, our survey data called for the subjective perceptions of managers in relation to RMI, CM, and the three performance measures. Although we used an approach well established in prior studies, future research should consider more objective measures such as cost, secondary data from customer satisfaction surveys, and other relevant firm metrics. Second, our study assesses a dynamic process at a single point in time. A more complete understanding of the relationships among the constructs may be accomplished using a longitudinal approach. Finally, research on counterfeit mitigation in the SC literature is largely underdeveloped. While our study makes an effort to illuminate this issue, future research should consider cost, service and firm performance in relation to the prevalence of counterfeiting at the industry- and firm-level. For example, would a firm with more counterfeit exposure at the industry-level have an increased focus on RMI? Would an organization with more experience dealing with counterfeiting at the firm-level have more extensive mitigation efforts in place and how might this impact cost and service performance? We call on scholars to explore these issues and many others in the emerging research stream of counterfeiting in the SC.

ABSTRACT

The goal of a firm is to make money. For this reason, firms show economic orientation in pursuit of long-term financial benefits and operational effectiveness. Recently than ever, manufacturing organizations are inclined towards designing and producing products using sustainable means. The purpose is to bring new products to the market that are environmentally sustainable and socially responsible. To study how economic priorities affect sustainability initiatives in new product development and innovations outcomes, this research presents a model with relationship between organization's economic orientation, sustainable product design activities and innovations performance of the firm. The empirical evidence is drawn from a panel survey of 282 US manufacturing firms. The results suggest strong relationships among the three constructs under investigation.

ABSTRACT

Aiming to investigate the role of Analytical Capabilities on Organizational Resilience this paper reports the results of a survey developed in companies located in the state of Espirito Santo/Brazil. Data analysis used structural equation modeling. The results show that the analytical capabilities positively influence organizational resilience.

KEYWORDS: Business Analytics, Analytical Capabilities, Resilience, Performance.

INTRODUCTION

Over the last three decades, the business environment has undergone radical changes driven by a series of breakthroughs and innovations that have also brought a variety of strategic and operational challenges to modern organizations in both public and private sectors (Doumpos & Zopounidis, 2016). One of the most fundamental challenges involves the design of resilient processes and the improvement of procedures for the planning and decision, which can provide a superior competitive advantage by improving operational efficiency, promote innovation and create added value for all parties. In this context, business analytics emerges as a powerful alternative to intelligibly reprogram organizational strategies and support the decision-making process based on facts and data (Doumpos & Zopounidis, 2016; Seddon, Constantinidis, Tamm, & Dod, 2016; Vidgen, Shaw, & Grant, 2017), especially in situations related to ruptures and vulnerabilities in the supply chain.

With the proliferation of Internet of Things (IoT) and IT systems like Enterprise Resource Planning (ERP), more and more data is generated, captured and stored. In this context, the survival and growth of many organizations nowadays are linked to their capabilities to effectively utilize large amount of data from different sources to drive their strategic and operational decisions. Thus, data analysis is becoming a critical factor of success (Barbosa, Vicente, Ladeira, & Oliveira, 2017).

Benefits of business analytics adoption are increasingly evident and robust. Business Analytics (BA) is a comprehensive term that comes from the industry. BA refers to the application of a wide range of data-driven analytical techniques and methods in different business domains (Chae, Yang, Olson, & Sheu, 2014). It is a relatively new term whose focus is on improving organizations' performance through a decision-making process based on fact and data (Appelbaum, Kogan, Vasarhelyi, & Yan, 2017; Bayrak, 2015; Bronzo et al., 2013; Cosic, Shanks, & Maynard, 2015; T. H. Davenport & Harris, 2007b; Holsapple, Lee-Post, & Pakath, 2014; Mortenson, Doherty, & Robinson, 2015; Seddon et al., 2016; Vidgen et al., 2017).

Organizations such as the Boston Red Sox, Netflix, Amazon.com, CEMEX, Capital One, Harrah's Entertainment, Procter & Gamble, Best Buy, amongst others, use business analytics to build their competitive strategies, guide their decision-making, and beat the competition. By applying their analytical capabilities to the data, these organizations identify the most profitable customers, accelerate product innovation, optimize supply chains, and manage to work with more competitive prices (Davenport & Harris, 2007).

This work explores the organizational analytical capabilities, identified as one of the five formative dimensions of BA (analytical capabilities, information quality, analytical technology, leadership commitment and analytical strategy) (T. Davenport, Cohen, & Jacobson, 2005). Such choice is justified by the fact that organizations continually need to make high quality decisions, quickly and clearly due to the dynamics involved in their operations. It is observed that it becomes easier for those who develop a set of capabilities to collect, aggregate, synthesize and analyze large volumes of data to support the decision-making process (Strategy & Leadership, 2009). Moreover, it is understood that analytical capabilities, once present in the organizational structure, can impact and interact with different resources and capabilities (J. B. Barney & Clark, 2007) and, consequently, influence organizational performance.

Thus, considering the interaction of such capabilities with the different resources and variables, it becomes relevant to analyze how organizational analytical capabilities relates to performance results in terms of resilience. The organizational resilience (Fiksel, Polyviou, Croxton, & Pettit, 2015; Pettit, Croxton, & Fiksel, 2013; Pettit, Fiksel, & Croxton, 2010) has currently received attention and emphasis from companies due to the continuous increase of vulnerabilities of its supply chains (Ambulkar, Blackhurst, & Grawe, 2015). In addition, the World Economic Forum indicated that more than 80% of the companies are now concerned with the development of supply chain resilience (Bhatia, Lane, & Wain, 2013) due to their harmful effects on operations.

Therefore, considering that organizational analytical capabilities are in a position to positively influence performance results, it is understood that they are hypothetically related to organizational resilience. It is based on such argument that this research effort will be directed to answer the following research question: *What is the impact of organizational analytical capabilities on organizational resilience?*

The article is structured in five main sections. After this introduction, it is presented in section two the definition and the theoretical relations between constructs, the research hypothesis and the proposed conceptual model. In section three, the methodological path is presented. In the fourth section the results are pointed out and the discussion developed in light of the researched theory. And in the fifth and last section, it summarizes the findings and final considerations of

the study along with the research limitations, proposing questions that may guide future research endeavors.

THEORETICAL BASIS, CONCEPTUAL MODEL AND RESEARCH HYPOTHESIS

Organizational Analytical Capabilities

Davenport, Cohen and Jacobson (2005) emphasize that analytical capabilities is one of the formative dimensions of BA in the organizational context, pointing out that although analytical software becomes increasingly popular and easy to use, companies that are beginning to become analytical oriented or are already competing on analytics still require substantial analytical capabilities from its members.

Analytical capabilities, according to Acito and Khatri (2014), refers to the use of a portfolio of analytical methods and tools, including those that support traditional ad hoc queries, inferential statistics, predictive analysis, simulation and optimization, aiming to support inquisitive, descriptive, predictive and prescriptive analysis at the managerial level, supporting the decision-making process (Acito & Khatri, 2014).

Delen and Demirkan (2013) brought another connotation for the respective dimension by considering the abilities to understand the needs of the business, to deal with large data – big data – usually complex and unstructured, and provide meaning to support the decision-making process.

Corroborating with the ideas of Delen and Demirkan (2013) and Acito and Khatri (2014), Holsapple, Lee-Post and Pakath (2014) argue that the key set of analytical capabilities is based on the combination of skills to manage evidence (facts/data) through models and logical and systemic reasoning. In this portfolio of competences lies the respective abilities: the use of quantitative and qualitative techniques and their combinations; the use of statistical techniques; systematic use of reasoning; management models of descriptive, explanatory, and predictive nature; and effective work based on evidence (eg, reports, databases, click- streams, documents, sensors, maps, etc.) (Holsapple et al., 2014).

Therefore, based on explained above and the definitions and a set of works on the subject (Acito & Khatri, 2014; Bayrak, 2015; Bronzo et al., 2013; Delen & Demirkan, 2013; Doumpos & Zopounidis, 2016; Gorman & Klimberg, 2014; Holsapple et al., 2014; Mortenson et al., 2015; Oliveira, McCormack, & Trkman, 2012; Sincorá, Carneiro, & Oliveira, 2015; Trkman, McCormack, Oliveira, & Ladeira, 2010; Troilo, Bouchet, Urban, & Sutton, 2015; Wagner, Brandt, & Neumann, 2016; Wilder & Ozgur, 2015), the conceptual and operational domain of the Organizational Analytical Capabilities construct is based on the synergistic inter-relationship amongst: i) Statistical Capabilities (referring to the ability to develop logical, critical and analytical reasoning about organizational reality from quantitative data); ii) Business Capabilities (inherent in the ability to identify problems, formulate and implement solutions, conduct decision making from facts and data, develop expression and communication compatible with the business environment); and iii) Capabilities in Information Technology (related to the competence to operate machines, information systems, and work with computational modeling), as represented in Figure 1.

Source: Adapted from Wilder and Ozgur (2015).

Organizational Resilience

In today's turbulent and uncertain environment, every organization in a supply chain is susceptible to disruption (Ambulkar et al., 2015; Ponomarov & Holcomb, 2009). The global reach of supply chains, products with shorter life cycles, and increasing customer requirements have made organizations aware that disruptions can cause undesirable operational and financial impact. In this way, disruptions such as the loss of a critical supplier, a major factory fire, or even an act of terrorism, have the potential to negatively affect revenue and cost. However, even if researchers and practitioners fully agree about its importance, what it is observed is that a vast majority of the companies still give limited attention to manage potential risks and do not have the capabilities to deal with them (Trkman, Oliveira, & McCormack, 2016), acting predominantly more reactive than proactive (Bhatia et al., 2013).

Based on this scenario, companies are now focusing on performance improvement and on the capacity to respond to the contingencies and risks, developing resilience in order to mitigate the effects of ruptures in their operations as they may result in negative consequences for the organization and for the whole supply chain (Ambulkar et al., 2015). Several researchers point out that resilient firms are less vulnerable to risk situations and are more able to deal with supply chain disruptions when they occur in more resilient processes (Blackhurst, Dunn, & Craighead, 2011; Fiksel et al., 2015; Pettit et al., 2013; Ponomarov & Holcomb, 2009; Rice & Caniato, 2003; Sheffi, 2005; Sutcliffe & Vogus, 2003; Weick, Sutcliffe, & Obstfeld, 1999; Wieland & Wallenburg, 2013; Wildavsky, 1988; Zsidisin & Wagner, 2010).

Although the theory about resilience is still in full development and discussion (Ponomarov & Holcomb, 2009; Wieland & Wallenburg, 2013), it was adopted an operational definition for the theme, as well as a set of key elements capable of characterize it in order to enable its measurement. Thus, based on Pettit, Croxton and Fiksel (2013, 2010), the conceptual domain built to delimit the Organizational Resilience construct consisted in the ability to survive, adapt and grow in the face of turbulent change. In other words, operationally, it refers to the abilities to discern and prepare for unexpected events (Anticipation), to respond to disturbances by

modifying processes and operations (Adaptability), and to recover from them, returning to the normal operating state (Recovery), maintaining control over the structure and functions and the continuity of operational processes at the desired level. This is, therefore, the essence of resilience, whether it is analyzed from the perspective of the supply chain or the organizational scope.

Theoretical Relationship Between Organizational Analytic Capabilities And Organizational Resilience

The company's resource-based view (RBV) provides an important basis for understanding how competitive advantage is created and sustained over time, given that firms gain competitive advantage through the accumulation of internal resources and capabilities that are rare, valuable, and difficult to imitate (Barney, 1991). These capabilities consist of attributes, skills, organizational processes, knowledge, and capabilities that enable an organization to achieve superior performance and sustainable competitive advantage over its competitors (Teece, Pisano, & Shuen, 1997).

In formulating the perspective of dynamic capabilities, Teece et al. (1997) argue that the capabilities of an organization can be renewed and developed to achieve congruence with the changing environment, making it possible to adapt, integrate, and reconfigure resources, organizational capacities, and functional competencies to respond to the challenges of the external environment. These dynamic capabilities, when approached in contexts of reaction to unforeseen situations, become important bases for the achievement of good Organizational Resilience performance results since they enable organizations to respond to the challenges imposed by the environment through the reconfiguration of their organizational resources.

Thus, when considering that the data and information generated by the organization also constitute resources (Chae et al., 2014; Cosic et al., 2015), it is assumed that when they are reconfigured based on the application of analytical capabilities, particularly to help the organization to cope with turbulence and uncertainty, such resources become rare, valuable, and difficult to imitate. Thus, the cross-referencing of data and information enabled by Organizational Analytical Capabilities allows the production of knowledge and insights to aid decision-making, envision future scenarios, capture opportunities, and identify problems and other possibilities that help the organization perform satisfactory resource reconfigurations to better respond to environmental challenges and therefore collaborate for better resilience outcomes.

Some of the crucial aspects of resilience are anticipation, adaptability, and recovery (Pettit et al., 2013, 2010), and it is interesting that these dimensions go together. According to Wieland and Wallenburg (2013), resilience can be improved by investing in the routine of sharing knowledge about relevant changes in the environment, in advance or when they occur. In this manner, to anticipate, it is necessary to acquire knowledge about possible changes that may occur in the future (Zsidisin & Wagner, 2010). To adapt to changes, which may or may not be predicted, it is necessary to reconfigure organizational resources, and to enable such reconfiguration, it is pertinent to control and evaluate the results of the implemented actions.

Therefore, the development of skills in anticipation, adaptability, and recovery can be positively supported in organizations that maintain an approach to use and share their data and information among different working groups that can be further used in the most diverse applications and business needs.

Finally, following these considerations, it is assumed that when Organizational Analytical Capabilities (composed of statistical capabilities, business capabilities, and information

technology capabilities) act in an integrated and coordinated manner, they can have a significant impact on Organizational Resilience. It is therefore argued that the better the integration between Organizational Analytical Capabilities, the greater the possibility of positively influence Organizational Resilience. This assumption results in the central hypothesis of the study: **H1:** Organizational Analytical Capabilities positively impacts Organizational Resilience.

Presentation of the Conceptual Model

The hypothetical model of this study contemplates constructs related to the conceptual domains of Organizational Analytical Capabilities (OAC) and Organizational Resilience (OR). As shown in Figure 2, the conceptual model of this study presents OAC as predictor of OR (the operationalization of each of the constructs of the model is presented in detailed fashion at the Appendix).

Figure 2 - Conceptual Model and related questions

METHODOLOGY

Design of the Survey, Source and Data Collection

This research was conducted based on a survey questionnaire. The questions were based on the literature, which served as a theoretical basis for the formulation of 34 measures - 4 related to the profile of the respondent/company and 30 related to the constructs studied -, the questionnaire used the Likert scale from 1 (one) to 5 (five) points.
In order to operationalize the OAC scales, we undertook a bibliometric study in seven databases of the area of Social Sciences (Ebsco, Emerald, Jstor, Sage, Scielo, Science Direct and Web of Science) to identify a set of manifest variables - with a higher incidence in the literature - that could measure the construct studied. The articles were collected searching for the term "business analytics" in the title, abstract and keywords that were published between 2004- 2015. For the measurement of the OR construct, it was adapted from the scale developed by Pettit et al. (2013), titled Supply Chain Resilience Assessment and Management (SCRAM), validated with data from seven global organizations from the industry and services sector.
After structuring the questionnaire, the 34 questions were validated by a group of experts (PhDs and managers) experienced in the conduction and application of surveys. These professionals contributed to the objectivity, clarity and coherence of the instrument, eliminating redundancies, ambiguities and content overlaps.
The data used in the survey was collected from online questionnaires applied to managers of companies associated to FINDES (Federation of Industries of the State of Espírito Santo) and CRA-ES (Regional Council of Administration of the State of Espírito Santo). The managers selected to participate in the survey were those who held positions related to production, logistics, marketing, sales, quality, purchasing and product development. It is worth mentioning that in order to guarantee the participation of key informants, contacts were made via telephone before sending of survey link to the email address informed by the respondent.
Espírito Santo is one of the states located in the Southeast region of Brazil. The state's economy is essentially based on traditional activities such as construction, extraction and processing of marble and granite, coffee agriculture, the garment industry, and tourism. In addition, the state has a solid position in the steel, furniture, mining, pulp, and fruit growing sectors, also emerging in new economic sectors such as oil and gas production and agro-tourism (Ferrari & Arthmar, 2011).
However, with the worsening of the current economic crisis in the country, the state has been forced to rethink alternatives for the readjustment of its development model. The changes imposed by the current political and economic situation generated turbulence and marked the trajectory of the sectors of industry, commerce, and service of Espírito Santo, compelling these sectors to incorporate into their operations and strategies technological and managerial innovations that are able to cope with the modifications that have been occurring in the internal and external markets.
This context provides the study with information about how the use of data and information by companies in Espírito Santo has been impacted their performances, based on the evaluation of their OAC and their supposed impact on the organizational resilience. Therefore, through the data collected in this scenario, it becomes possible to identify viable paths to generate a competitive advantage sustained through informational resources and the application of analytical capabilities.
Having that said, the criteria used to calculate the sample were recommended by Hair, Hult, Ringle and Sarstedt (2017) for the use of Structural Equation Modeling (SEM), based on the partial least squares (PLS) algorithm, which consisted of the following conditions:

a) The value of the sample should be 10 times ≥ the number of indicators of the construct that has the highest number of formative indicators of the measurement model; or

b) The sample value should be 10 times ≥ the number of the greatest number of paths directed to a particular construct of the structural model.

Therefore, based on the respective criteria, a minimum sample size of 50 respondents was identified. However, 83 questionnaires answered were collected from FINDES respondents, and the remaining 211 respondents were collected from CRA-ES. After performing a preliminary analysis to identify equivalence issues and avoid sample problems with the data collected, the final sample consisted of 288 valid cases.

Data Processing

According to Knoppern et al. (2015), interviewee data from heterogeneous groups should not be grouped and/or compared without first examining whether they are equivalent, since ignoring questions of equivalence can lead to ambiguous and erroneous conclusions.
In order to check the equivalence between those two groups (FINDES and CRA-ES), a multi-group analysis was performed (Ringle, Wende, & Becker, 2014). The equivalence test consisted of three steps: the tests of configural equivalence, metric and scalar. The configural equivalence was verified with all loads of the indicators demonstrating significant to the same factors between the groups. Similarly, the metric equivalence test showed no statistical difference between the factor loads of each group, with all p-values of the confidence interval between 0.025 to 0.975 (Sarstedt, Henseler, & Ringle, 2011). Finally, through the data obtained by the bootstrapping technique ran with 5,000 sub-samples (Hair, Sarstedt, Ringle, & Gudergan, 2018), the scalar equivalence test revealed that all p-values of the difference between groups are not significant at a 95% confidence level (Table 1). This result shows that there is no statistically significant difference between groups, thus indicating the possibility of grouping the data.

Table 1 – Scalar equivalence Test using PLS-MGA technique

PLS-MGA	**Path Coefficients-diff (GROUP (1.0) vs GROUP (2.0) |)**	***p*-Value (GROUP (1.0) vs GROUP (2.0))**
OAC → OR	0,002	0,503
Statistical Capabilities → OAC	0,024	0,550
Business Capabilities → OAC	0,231	0,220
IT Capabilities → AOC	0,242	0,787

PRESENTATION AND DISCUSSION OF RESULTS

Results of Descriptive Statistics

The descriptive statistics for the profile of the respondent and companies that composed the sample was based basically on the frequency distribution and the graphical representation of these variables. Related to the “Position of the Respondent” in the company, half of the respondents belong to strategic positions (sum of the functions of president 4%, director 16% and manager 29%), followed by analyst 16%, assistant 13% and other positions 22%. This sample composition is beneficial for the study, since they denote greater knowledge about fundamental questions of the study and capture greater understanding of the organizational functioning due to the position they occupy, above all, positioned in areas related to operations. Regarding the variable “Business Sector”, it was possible to observe that 69% of the sample came from the service sector, followed by commercial companies (19%) and industrial (12%) respectively and more than 70% of the companies have more than 5 years age. Considering the “Size”, following the definition given by the National Bank for Economic and Social Development of Brazil (BNDES) based on annual revenues, 32% of the companies participating in the study are micro-sized, followed respectively by small companies (30%) and the minority, represented by 10%, refer to medium-large and large-sized companies.

Results of the Structural Equation Modeling

The structural equation modeling analysis technique was used to validate the proposed conceptual model, as well as verify the hypothesized relationship. Initially, based on Smart software PLS-SEM 3.0 (Ringle et al., 2014), it was possible to carry out the validation tests of the measurement model (convergent validity test, collinearity test, and significance and relevance test). Thus, after removing the indicator q6 - referring to the Statistical Capabilities -, since it presented high collinearity within the set of indicators in which it belonged, the results showed that all relations between indicators and constructs were considered valid within the quality criteria.

With the measurement models validated, we proceeded to validate the structural model of the research (the direct and indirect relations between the constructs of the model). Initially, when carrying out the multicollinearity test, which evaluates whether the constructs are highly intercorrelated, it was identified that there are no problems of this nature, which indicates a good quality measure for the general adjustment of the theoretical model, since they were adequately defined, having a robust conceptual coverage and without shadowing with other theoretical concepts.

The Significance and Relevance *t* test, with 287 degrees of freedom and 5% significance level, using data from Bootstrapping, demonstrated that the hypothesis **H1**: Organizational Analytic Capabilities positively impacts Organizational Resilience was accepted since it is statistically significant, as can be seen in Table 2.

Table 2 - Total effects

Direction of the Path of Coefficient			Path Coefficients Values	*p-value**
Statistics Capabilities	→	OAC	0,071	0,477
Business Capabilities	→	OAC	0,520	0,000
IT Capabilities	→	OAC	0,466	0,000
OAC	→	OR	0,785	0,000

* The path coefficients significance of the 1st and 2nd order constructs, at the p-value level <0.05, when submitted to the t-test with the Bootstrapping technique.

Source: Prepared by the authors based on the research data.

Also, through the t test, it is possible to emphasize that only the paths coefficient of Business Capabilities (0.520) and Capabilities in Information Technology (0.466) have been shown to maintain statistical significance in relation to OACs, thus revealing that first-order constructs are the ones that contribute the most to indirectly impact OR behavior.

This conclusion reinforces the assumptions of Wieland and Wallenburg (2013) and Zsidisin and Wagner (2010) that organizational resilience can be improved by investing in the routine of sharing knowledge about relevant changes in the business environment, in advance or when change happens. Corroborating this discussion, experts from different regions and sectors of the economy, invited by the World Economic Forum (Bhatia et al., 2013) to discuss measures to build resilience, recognized that priority number one was to improve the sharing of information among the different actors in the chain. Such line of thought stresses that the expansion of the use of data sharing platforms to identify and respond to risks can enable the visibility of information, providing early warning of problems and allowing decentralized solutions.

It is also reflected in the Information Technology Capabilities that companies are increasingly targeting constant investments in technology platforms, ERP systems and corporate management solutions. It turns out an incipient paradigm shift, that is, the technological infrastructure has not only served to store data without the effective contribution to the managerial process, but has effectively contributed to the business needs, since it has been identified among the companies researched the organizational competence to operate machines, information systems and work with computer modeling.

The results of the test also point to the importance of Business Capabilities, since their presence in the business structure indicates that the organization is able to understand its business needs, interpret the analyzes performed in large databases and provide meaning supporting the decision making and revealing opportunities that emerge in the business routine, with the potential to communicate and share them whenever they are needed (Acito & Khatri, 2014; Bayrak, 2015; Cosic et al., 2015; Cybulski, Keller, Nguyen, & Saundage, 2013; Delen & Demirkan, 2013; Gorman & Klimberg, 2014; Informs, 2014; Mcclure & Sircar, 2008; Mortenson et al., 2015; Ranyard, Fildes, & Hu, 2015; Rasmussen & Ulrich, 2015; Troilo et al., 2015; Wilder & Ozgur, 2015).

However, the explanation that the Statistical Capabilities did not show a significant antecedent to OR may be in the reality of the organizations researched. Because it does not have all the analytical capabilities that have been developed to fuel the decision-making process, most decisions are based on subjective knowledge of the business rather than on quantitative and numerical data. Possibly, the companies that composed the study are not familiar with the extraction and use of data of quantitative nature due to the lack of skills to work with descriptive, predictive and prescriptive analyzes, thus revealing the need for investments to foster the development of logical reasoning based on critical and analytical information about organization.

Despite of this results, it is important to highlight that Fahimnia et al. (2015) found that quantitative risk analysis is rapidly expanding across studies and research related to the subject, quantitative and analytical models - inherent in statistical skills - (i.e. mathematical models, optimization, simulation, analysis decision-makers and others) are being used to

manage both organizational and supply chain risks, thus strengthening the capabilities of anticipating organizations to identify potential risks and barriers.
Nevertheless, from the Variance Coefficient (R^2) evaluation, it was verified that 61.6% of the variation that occurs in the behavior of the endogenous OR construct can be explained by the variation that occurs in the OAC. Thus, it was concluded that if a manager wants to develop the analytical capabilities of her company, she should make efforts to improve its capabilities, especially in business (inherent in the ability to identify problems, formulate and implement solutions, data and facts, developing expression and communication compatible with the business environment) and in information technology (related to the ability to explore dataset, sanitize data, integrate dataset and build big data environments). In this way, OACs can act as medium- and long-term performance driver, helping companies to design and develop new capabilities, especially in terms of resilience, improving with time, skills and competitiveness standards.
In a managerial decision, for example, the relevance of this data is that the company can choose to invest on the promotion of analytical skills since it will benefit the company's performance, especially regarding its capacity to respond to its stakeholders in situations of turbulence, challenges and uncertainties, thus contributing to deliver satisfactory results to both its clients and shareholders.
It is understood that the advantages obtained by the organization from the continuous use of its data and information, which are successively generated and circulated in the organizational environment, support business operations and decision-making processes and help to leverage resilience levels achieving satisfactory and meaningful performance results.
Therefore, organizations that understand the value of analytical orientation through the development of their analytical capabilities, will better manage their business problems specially when they experience turbulence and disruptions in their operations. In this way, they will be in a better position to build and strengthen their capabilities in resilience and, therefore, to achieve superior performance results (Sheffi, 2005).
The findings are also reinforced by experts who claim that optimization requires discipline, the use of business analytics and the involvement of a broad range of business, technology, and executive work both within and outside the organization (Bhatia et al., 2013). Therefore, to mitigate the risks, vulnerabilities and ruptures, it is necessary to encourage organizations to follow agile and adaptive strategies to improve resilience (Bhatia et al., 2013; Fiksel et al., 2015). This opportunity is verified through the application of analytical practices in the business routine and in the day-to-day chain, given that the analytical approach itself allows actions to intelligibly reprogram organizational strategies and operations, facilitating the development of capabilities to compensate or mitigate vulnerabilities.

CONCLUSIONS

The research results present relevant findings, both from the practical and academic point of view, by presenting that organizational analytical capabilities act as a critical and predictive element to determine organizational resilience.
Thus, the results of the research contributed to clarify the Organizational Analytical Capabilities construct, which has emerged since the last decade as a relevant topic for the scientific community in studies related to Business Analytics. Regarding the managerial context, the effort of this research made it possible for managers to understand what analytical skills are critical to be developed and articulated by the work teams. Moreover, it demonstrated the importance of

valuing and developing capabilities under statistical analysis, given that empirical research has revealed that such capabilities allows leveraging and influencing the behavior of resilience.
In seeking answers to the central problems of the study about the impact of organizational analytical capabilities on organizational resilience, the answer obtained was that the impact for this relationship is positive, therefore, companies that have an orientation focused on the analysis of their data, will be better able to go through situations vulnerabilities. Faced with these findings, we can depict that the analytical approach, besides being able to act as a resource for other organizational variables, it is also an important strategy for the development of resilience, since it allows intelligently reprogramming business activities when potential risks, ruptures or vulnerabilities are detected.
In addition, the study also showed the need to invest not only in software and hardware, but also in the development and recruitment of qualified professionals to undertake the analysis of the vast amount of information that organizations and society today deal with. Thus, without such properly prepared individuals, of course, many economic sectors will be missing the opportunity to improve their performance and take competition in their markets based on data analysis.
Another implication of the research lies in the understanding that business analytics can generate business value from structured and highly analytical decision-making processes (Seddon et al., 2016; Sharma, Mithas, & Kankanhalli, 2014) and not only limited to the treatment and analysis of data and information (Emblemsvåg, 2005). The refinement and use of resilience capabilities can also generate benefits at the organizational and network level, especially when attention and resources are directed to the generation of value over time and not only to protect themselves from risk (Trkman et al., 2016).
In addition, research findings also have clear implications for both academics and practitioners. Over the last few years, disruptive events have significantly increased the internal and external risks of organizations (Hohenstein, Feisel, Hartmann, & Giunipero, 2015). Thus, the proposed conceptual model for measuring analytical capabilities and organizational resilience provides an excellent managerial orientation to build analytical practices and resilience in various business areas. The component elements of the constructs can be used to evaluate the level of use of the data and information by the organization, as well as to measure resilience results in order to implement actions to strengthen its own resilience and to identify the priority areas in which the should be prioritized.
Thus, measuring resilience, whether in organizations or in supply chains, reveals itself a relevant managerial need, since this attitude supports the knowledge and understanding of managing unexpected risk events, as well as helps companies to assess their ability to respond to disruptions. Therefore, measuring the resilience level of business operations influences decision makers in prioritizing the development of resilience capabilities needed (Hohenstein et al., 2015).
An example of a company that is already working on this dynamic response to possible disruptions using different mitigation tactics is Procter & Gamble, which by applying monitoring tools has increased its resilience capabilities, bringing together, updating, and using data and information regarding critical points in its supply chain (Sáenz & Revilla, 2014).
Likewise, at the supply chain level, associations are created around the world to protect themselves against possible vulnerabilities in which they are sensitive. An example is C-TPAT (Customs-Trade Partnership against Terrorism) which is a voluntary initiative that creates joint security protocols for member companies to strengthen and improve US supply chains. TradeXchange, on the other hand, is an association of Singapore that engages business partners to collaborate in logistics activities, allowing flexibility and quick collective response to

the anomalies that emerge from the supply chain. Also, associations such as the Kyohokai were formed aiming at mutual learning at Toyota Motor Company (Bhatia et al., 2013).
Regarding the limitations, because it is an essentially quantitative research, the study presented restrictions on a qualitative analysis of the queried questions. If such an analysis had been possible, more explanatory and detailed results would possibly be obtained. Although this is a recognized restriction, the proposal to carry out a quantitative research was met within the statistical criteria, as well as validation of the proposed conceptual model and verification of the hypothesized relationship.
Despite this set of restrictions, the study of CA (analytical capabilities) represents expressive contours for the field of research, especially in Decision Making. Since only a few years ago the topic was effectively discussed in organizational studies and in management science. Taking root as a new teaching and research arena, publications are increasingly growing and popularizing, contributing for the evolution of the analytic movement. Therefore, the analytical approach that first emerged within the context of consulting and evolved over a short period of time within the applied social sciences has received increasing attention from the scientific community interested in understanding its phenomenon and its impacts and configurations within organizations, thus justifying in part, the validity of the study performed here.
It is necessary to suggest future work on the subject. Thus, it is possible to evaluate the extent that the Process Management construct, for example, may prove significant to positively impact both organizational and supply chain resilience. As well as analyze how its relationship with the analytical capacities improves the development and the reinforcement of the resilience. This investigation is valid, given the suspicion that the analytical capabilities can leverage the influence they exert on the performance of the organization when being undertaken in the business routine, especially supporting the management of business processes and obtaining relevant information about the processes itself (Bronzo et al., 2013; Galbraith, 1974; Muehlen & Shapiro, 2010).
In addition, it is recommended that new studies can be developed based on the validated model in this study by taking a qualitative approach. An alternative approach of qualitative nature can bring new and useful information regarding the relationships between the constructs investigated in the present research, considering, for example, interviews and participant or non-participant observations on decision-making practice in organizations.

APPENDIX

Figure 3 – Research constructs and indicators.

FORMATIVE CONSTRUCTS: SECOND-ORDER	FORMATIVE CONSTRUCTS: FIRST-ORDER	ITEMS/ FORMATIVE INDICATORS *
ORGANIZATIONAL ANALYTICAL CAPABILITIES (OAC)	Statistical Capabilities	▪ inquisitive analysis; ▪ descriptive analysis; ▪ predictive analysis; ▪ prescriptive analysis; ▪ Improving the decision-making process (reflexive indicator).
	Business Capabilities	▪ communication of problems; ▪ data translation; ▪ interpretation of analyses;

FORMATIVE CONSTRUCTS: SECOND-ORDER	FORMATIVE CONSTRUCTS: FIRST-ORDER	ITEMS/ FORMATIVE INDICATORS *
		▪ decision-making; ▪ Improving the decision-making process (reflexive indicator).
	Information Technology Capabilities	▪ data exploration; ▪ data hygiene; ▪ data integration; ▪ creation of environments; ▪ Improving the decision-making process (reflexive indicator).
ORGANIZATIONAL RESILIENCE (OR)	Anticipation	▪ identification of risks; ▪ monitoring deviations; ▪ early recognition of disruptions; ▪ recognition of opportunities; ▪ Good predictive capacity (reflexive indicator).
	Adaptability	▪ modification of processes; ▪ simulation of processes; ▪ development of technology; ▪ use of continuous improvement; ▪ Good capacity for adaptation (reflexive indicator).
	Recovery	▪ organization of response teams; ▪ communication of information; ▪ managing public relations; ▪ mitigation of effects of interruption; ▪ Good capacity for recovery (reflexive indicator).

Source: Prepared by authors based on research data.

*In the research instrument, there are 30 indicators used to measure the second-order constructs of OAC and OR. These indicators were derived from the items presented in this table. Thus, for each item present in the table, there is 1 (one) corresponding question in the research questionnaire.

ABSTRACT

Literature indicates that 42% of U.S. firms have integrated social media in their business strategies. Firms now use social media as a tool to interact with customers for sharing information and responding quickly to their needs. This study explores the role of social media in customer/supplier management and customer satisfaction.

KEYWORDS: Social Media, Customer Relationship Management, Supplier Relationship Management, Customer Satisfaction, Social Networking Perspective

INTRODUCTION

Customer satisfaction is a central tenet of management (Yeung and Ennew, 2000). Every organization strives to achieve great customer satisfaction because it leads to repeat purchase, brand loyalty reduces customer compliant and increases the profitability of organization (Churchill and Surprenant, 1982). In the early 2000s, customer relationship management (CRM) became very popular among managers to help improve customer relationship and satisfaction (Trainor et al., 2014). Today, managers and employees are charged with the exceptional task of combining nascent technologies with existing management systems, processes, and capabilities to foster customer relations and improve customer satisfaction (Trainor et al., 2014). This collaboration has led to a better framework not just to improve customer relations, but to improve customer satisfaction.

CRM is a “system that collects data from a number of customer-facing activities to help an organization better understand its customers so that it can better match its products and services to customer needs and thereby increase sales” (Hill, 2017, p.104). It can be viewed as a “core organizational process that focuses on establishing, maintaining, and enhancing long-term associations with customers” (Jayachandran et al., 2005, p. 3). CRM serves as a fusion of people, processes, and technology working together to understand a company’s customers. Hence, it is an integrated approach to manage customer retention, build customer relationships, and improve customer satisfaction (Chen and Popovich, 2003).

In the last decades, the nature of competition among companies has shifted towards supply management and the struggles management face when choosing and managing the relationships with their suppliers. Thus, the supply chain management is now viewed not just as means of getting products and services to the customers but also as a way of enhancing key outcomes - customer satisfaction (Hult et al., 2007). Researchers have begun to examine supplier relationship

management (SRM) and its effect on firm performance and customer satisfaction (Tan et al., 1998; Li et al., 2006). According to Webb (2017), SRM helps managers plan and manage all interactions with suppliers in an attempt to determine what supply chain categories are essential and what avenues/strategies are necessary to manage them efficiently. Studies (Croom et al., 2000; Choi et al., 2006; Hult et al., 2007) explain the importance of supply chain management in management research as well as in a firm. These studies suggest that in order to sustain competitive advantages in the market, companies must manage their supply base efficiently and with caution so as not to lose their competitive position in the market.

Since the internet revolution in the 1990s, our lives and the way we communicate have been significantly changed. Decades later, with the advent of social media, people can come together, share information, generate ideas, and give feedbacks concerning a company's product or service (Madabushi, 2014). The information shared is almost instantaneous hence, companies have resulted to investing lots of money to preserve their brand by continually communicating with customers, listening to complaints and accepting feedback all in an attempt to satisfy their customers and improve company performance. Reports show that companies are increasingly spending time and resources on their social media technological use. Statistics from eMarketer in 2015 projected companies' spending on social network advertising globally to be $35.98 billion in 2017 (representing an increase of 33.5% from 2014) (Emarketer, 2015, April). Statista projected that social media marketing in the United States would amount to $13.5 billion in 2017(Statista, 2018).

Despite the extant literature (Arsenault, 2014; Parveen et al. 2015; Rossmann et al., 2017) on the importance of social media on business operations, the effect of social media on customer satisfaction remain underexplored. There is a a considerable amount of research (Sousa et al. 2006; Weinberg and Berger, 2011) that show that social media complements a firm's strategy to produce more successful results. However, "whether firms are better off using social media" is still up for debate (Rossmann et al. 2017, p. 3950), so also has the effectiveness of social media on CRM and SRM remained underexplored" (Trainor et al. 2014). Academic research on social media has remained incomplete – not providing discerning analysis on the various objectives of social media and the impact it has on organizations and its customers (Parveen et al. 2015, p. 68). Further, organizational-level research on social media usage and its relationship with CRM and SRM is still in its infancy (Lovejoy and Saxton, 2012; Parveen et al., 2015). Thus, the purpose of this study is to explore the role of social media in the relationship between CRM, SRM, and customer satisfaction.

In the next section, we review the literature on Social Media, CRM, SRM and various studies related to the subject area, followed by hypotheses development and research methodology. Finally we discuss theoretical and managerial implications of this study.

LITERATURE REVIEW

Customer Relationship Management

Studies (Heskett et al., 1990; Blanchard and Galloway, 1994; Hallowell 1996) suggest that customer satisfaction is a reflection of customer's perception of the value obtained from a product or service received. This perception affects customers continued relationship with the company - attachment to a product or service (Fornier, 1994), and product recommendation (Yi, 1990). This also reduces customer acquisition cost and increases company revenue (Reicheld and Sasser, 1990). In a survey of 200 top managers, 142 of them agree that customer satisfaction is a very effective tool that helps manage and monitor their business (Farris et al., 2010). Customer

Relationship Management (CRM) centers on helping managers and employees develop and manage long-term relationships with their customers in other to improve customer satisfaction (Jayachandran et al., 2005). CRM is an all-inclusive approach that combines technology, process, and all business activities around the customer (Anton, 1996; Anton and Hoeck, 2002; Feinberg and Kadam, 2002). It is a management technique that focuses on individual customer, and requires firms be structured around customers, rather than products (Chen and Popovich, 2003). Hill (2012, p. 93), describes CRM as a "system that collects data from a number of customerfacing activities to help an organization better understand its customers so that it can better match its products and services to customer needs". Further, evidenc supports that CRM provides incentives for employees to break down functional barriers and encourages information sharing which helps to improve customer satisfaction (Chen and Popovich, 2003; Day, 2003; Cooper et al., 2008; Trainor et al., 2014). It also supports the coordination of activities with customers, enables a firm to understand its customers better, interact with them, and respond quickly to their needs (Day, 1994). Therefore, a good CRM system helps management develop a deeper understanding of customer buying behavior (Hill, 2012) and as a result, influences customer relationship by building on established long-term customer relationships thereby increasing customer satisfaction.

Supplier Relationship Management

As competition increased and markets became global, so did the challenge of product and service distribution. Companies were faced with the task of getting products and services to customers on time and at an affordable price (Li et al., 2006). Managers began to realize the importance of supply chain management to stay competitive and increase profitability. The effective management of buying raw materials, integral parts, and finished goods to meet the needs of the customer is the very core of competitive supply chain management (Ross, 2004). With supply chain management, the main objective is to create synergy within the supply chain to achieve larger benefits than those achieved by an individual firm in the chain acting independently (Vollmann and Cordon, 1998). The goal of which is to "create distinctive competencies—for the chain—where the whole is greater than the sum of the parts" (Vollmann and Cordon, 1998, p. 687).

Managing these relationships to achieve the maximum potential is a daunting task as the buying/purchasing company is not just faced with the challenge of managing single purchases with different suppliers instead, it is faced with the challenge managing several purchases from multiple suppliers (Moeller et al., 2006). The goal of SRM is to ensure that both information and material, flow seamlessly throughout the supply chain in an effective competitive manner (Feldmann and Müller, 2003; Childhouse and Towill, 2003). SRM involves taking on activities that set up, develop, stabilize and dissolve relationships with suppliers in other to create and enhance value for the company and its customers (Moeller et al., 2006). It strives to enhance relationships with suppliers to increase collaboration, reduce cost, improve quality, reduce inventory, increase value and reduce risk (Hill, 2012). Paparoidamis et al. (2017) found that suppliers benefit from maintaining and building a strong, loyal customer base. For the suppliers, they can maintain a stable stream of revenue; it reduces customer acquisition cost, and ultimately increases profitability. The benefits of using SRM are enormous; reduces cost, increase efficiency, minimizes price volatility, consolidates supply chain, and also helps in the continual improvement of operations (Shin et al. 2000; Davies 2018). With SRM, managers can plan and manage all interactions with suppliers in an attempt to determine what supply chain categories are important and what avenues/strategies are necessary to manage them efficiently (Webb, 2017). Jap (1999)

found that active collaboration with suppliers can help the purchasing company reduce unnecessary inventories, reduce cost, increase business and information flow about competitors for suppliers and increase customer satisfaction. Beamon (1999) found that on-time delivery was an essential variable that affected customer satisfaction. Also, Heikkilä, (2002) found the delivering products to customers on time increases customer satisfaction.

Social Media

Social media has become a critical concept for many business practitioners (Kaplan et al., 2010). Managers now use social media as a tool to improve company profitability as well as a way to interact with customers - to meet their needs and respond quickly to their wants. Social media can be described as an “online resource that people use to share ‘content’: video, photos, images, text, ideas, insight, humor, opinion, gossip, news — the list goes on” (Drury, 2008, p. 274). Table 1 summarizes articles that show how social media has been used in various fields and in numerous capacity to improve business operations. Studies suggest that social media enhances business operations by improving customer satisfaction and facilitates the use of these management systems.

Table 1: Major Studies on Social Media, Customer Relationship Management, and Customer Satisfaction			
Study	**Objective**	**Type & Sample**	**Key Findings**
Gallaugher and Ransbotham, (2010)	How social media facilitates customer dialog	Empirical/ meetings and interviews with Starbucks social media team and secondary sources – newspapers	Using social media helps identify problems and foster innovation
Heller and Parasnis (2011)	Argue for the use of social media in conjunction with customer relationship management (CRM).	Empirical/ 1000 customers worldwide and 350 executives	Consumers have a vested interest in getting tangible value. However, businesses may confuse their need for customer engagement with what motivates a customer to engage
Sashi (2012)	Describes how social media can help practitioners develop close relationships with customers	Conceptual	Designed a model to help improve our understanding of customer engagement and gives strategies that can form the foundation
Rishika et al. (2013)	Studies the result of customers' involvement in a firm's social media endeavors and its effects on firm activities	Empirical/ 394 customers from the customer base of a large specialty firm in northeastern United States	Customer involvement in firm's social media endeavors increases customer visits
Rapp et al., (2013)	Develop a framework that provides insight into how social media affects sellers, retailers and customers.	Empirical/ 3 level data set from suppliers, retail managers, and consumers	Social media affects brand performance and customer loyalty
Hajli (2014)	How social media facilitates customer engagement, influences buying intention and trust	Empirical/ 237 members of social networking sites in London and UK	Social media had a positive effect on trust which in turn influences consumer buying intention

Sano (2014)	How social media use in the tourism industry increases customer satisfaction and affects behavior intentions	Empirical/ 4,731 respondents accessing or using travel agencies' social media	Social media affects customer satisfaction stronger than it does behavior intention
Della Corte et al., (2015)	Describe how social media facilitates customer engagement and promotes service innovation	Empirical/ secondary web data	Social media allows companies monitor customers' comments and their level of commitment to a product.
Agnihotri et al. (2016)	To examine how salesperson's information dissemination behaviors affect the relationship between social media and customer satisfaction	Empirical/ 111 salesperson-reported data, within a business-to-business (B2B) context	Social media influences communication behaviors, and strengthens responsiveness/customer satisfaction.
Maecker et al. (2016)	Examines how social media channels affects customer relationship management.	Empirical/ 334,111 customers from a mobile phone service provider in a major European country	Social media facilitates upselling efforts and reduces customer attrition
Elena (2016)	Examines how social media promotes the growth of customer relationship management	Empirical/ case studies and survey of 87 business executives/managers from Romania.	With social CRM, organizations can build better relationships with customers, gain their trust and increase their confidence
Liang et al. (2016)	Examine how social media influences customer satisfaction	Conceptual	Social media affects buying behavior and customer satisfaction
Khan et al. (2017)	Examine the approach used by Bank Muscat customers to make suggestions and complaints; and to explore the problems these customers face while reaching out the bank via Social Media.	Empirical/ 234 respondents from the branches of Bank of Muscat in Oman	The Bank uses social media to disperse important information to customers. Suggestions and complaints made through Social Media received a quick response. Trustworthy information and Responsiveness affect Customer Satisfaction.

HYPOTHESES

The Effect of Social Media on CRM and Customer Satisfaction

Technological changes gave rise to the use of social media which is changing the world on a daily basis. Social media is used for information sharing and seeking, entertainment, and expressing an opinion about a product or an issue (Whiting et al. 2013). Never before have companies come so close to engaging with their customers in such a timely manner (Woodcock et al., 2011). Agnihotri, et al., (2016, p. 1) describes how customers are 'asked to 'like' companies on Facebook, to 'follow' companies on Twitter, or to 'connect' via LinkedIn". Hence, he suggests that customers have become more connected to companies and more knowledgeable about company products making them powerful agents in the buyer and supplier relationships. With the emergence and versatility of social media, "many businesses began to determine how to reap the potential benefits of this resource which includes building better relationships with customers, promoting their company brand as well as improving customer satisfaction" (Sano, 2014, p. 46). Social media has become a crucial communication tool for people to communicate with friends and families, and for companies to communicate with customers (Sano et al., 2016). A study by Insites Consulting (2011) on 399 randomly selected European and U.S. companies found that 80% of the companies have adopted some social media initiatives and 42% of these companies had fully integrated the use of social media in their business strategies. Another study by (Nielsen, 2010) found that consumers spend 25% of their internet time of social networking sites and more than half of online shoppers interact with retailers online (Rapp et al., 2013).

Based on the social networking perspective, which can be described as "a set of nodes (e.g., persons, organizations) linked by a set of social relationships (e.g., friendship, transfer of funds, overlapping membership) of a specified type" (Laumann et al. 1978, p. 458), we now have social customers - who are able to share reviews and give feedback about a company's product or service. Hence, companies are forced to deal with the continuous growth of social media where customers share their experiences and opinions on a much larger scale and where company reputations can be ruined very quickly. To do this, they now have to find ways to navigate the market effectively and come up with strategies that build better relationships with the customer (Acker et al., 2011). With the constantly changing business environment, companies are faced with the influential power of social media and are now using the social media platforms in various fields such as CRM (Sano et al., 2016). Social media impacts an organization's CRM capability because it establishes an environment that fosters customer engagement, collaborates and enhance customer relationships (Trusov et al., 2009). Companies that use social media can increase their product or service awareness, accentuate their plan to engage in interactive dialogue, thereby augmenting the effect of CRM capabilities. Also, companies that adapt quickly to technological innovations tend to have higher performance (Han et al., 1998). The study by Agnihotri et al., (2016) on the impact of social media on customer satisfaction found that social media does plays a vital role in communicating with customers. However, it does not have a direct effect on customer satisfaction; rather, it is an antecedent that enhances a salesperson behavior to increase customer satisfaction. They emphasize setting clear boundaries on what can be shared and how employees interact with the company customers.

Using social media platforms, companies have been able to reduce customer complaints (Acker et al., 2011). The online community that Best Buy has is a perfect example of the impact social media has on customer satisfaction. In the last decade, Best Buy online community (made up of staffers and other community members) had 2.5 million visitors and approximately 80 million messages on questions they had about a product or service. Only 5% of customers questions

were answered by Best Buy staffers, most of which were answered by the online community. As a result, Best Buys saved $5m (Acker et al., 2011). iPhone call centers also experienced fewer calls as a result of their FAQ page viewed more than 84,000 times. Hence, if social media is effectively managed, and used in conjunction with CRM, it can generate not only financial rewards but improve customer satisfaction (Acker et al., 2011). The study by Wang and Kim (2017, p. 15) shows that social media has more "direct impact on brand communities, produces higher response rates and customer engagement levels than traditional marketing methodologies that focus only on the firm–consumer relationship." According to Trainor et al., (2014) social media use increases firm effectiveness by providing a better understanding into the underlying relationships between the social networks existing customers and new prospects and also by facilitating internal and external collaborations which lead to improved customer solutions (Trainor, 2012). In the light of all arguments above, it is rationalized that the use of social media will positively moderate a company's CRM capability of interacting with customers in collaborative conversations and enhancing customer relationships. As such, we suggest that the relationship between CRM and customer satisfaction would be stronger especially for firms that use social media technology extensively. Therefore, the following hypothesis is proposed to empirically test in this study:

H1: *Social media positively moderates the relationship between CRM and customer satisfaction*

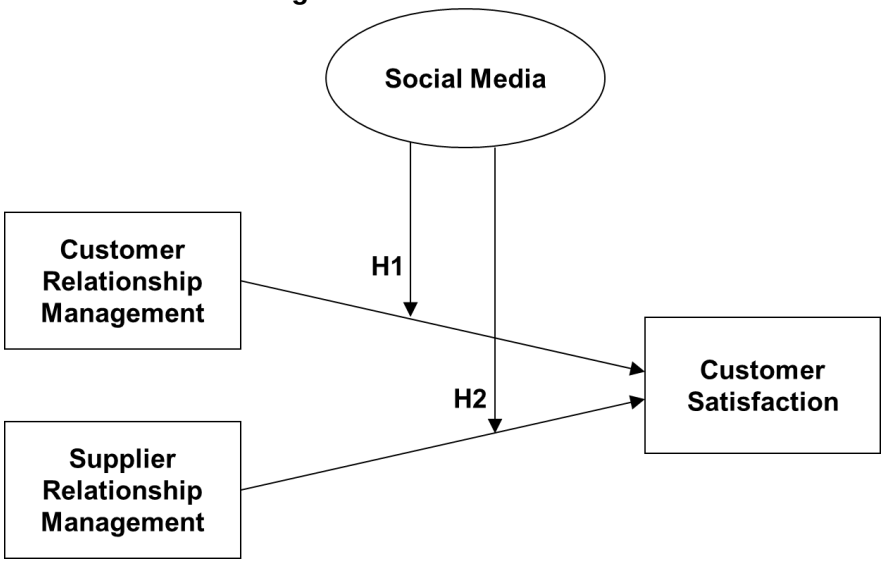
The Effect of Social Media on SRM and Customer Satisfaction

Studies on the relationship between social media and SRM show that "the goal must be to create distinctive competencies—for the chain—where the whole is greater than the sum of the parts" (Vollmann and Cordon, 1998, p. 687). The use of social media has become more paramount than ever and it has raised a lot of interest. Many companies now use social media as a strategic marketing tool in order to increase their brand visibility and awareness. However, what about using this new trend in conjunction with "Supplier Relationship Management"? (The Social Media becomes, 2010). The literature on SRM and its impact on customer satisfaction is very scant. Based on the few studies done on this topic (Rapp et al., 2013), the use of social media with SRM should increase customer satisfaction. This is because, managers and suppliers are able to collect information and give feedback to customers in a timely manner, while also allowing companies adapt to the changing needs and taste of customers (Brin, 2011). The effective management of a firm's suppliers thus has a tremendous effect on its competitive position, as well as its ability to fulfill its customers' needs (Song et al., 2014; Omoruyi et al., 2016). Zappos, one of the online retailers uses social media to interact constantly with customers, thereby developing real relationships and increasing customer satisfaction (Porterfield, 2011). T-Mobile, one of the large wireless tech giant, is known for its use of social media to interact constantly with customers and as of 2014, its Facebook page had a response rate of 91.13% (Patel, 2015). Gil Saura et al. (2008) found customer satisfaction to be positively related to timeliness-a factor of effective supply management.

The increasing use of social media in management means that social media is relevant in the purchasing perspective as well as in the aspect of increasing consumer satisfaction (Ylimaula and Ulkuniemi, 2013). With social media, companies can improve their communication strategy, exchange ideas with customers who can participate in product development and then create products based on customer need (Bughin et al. 2009). This in turn, helps to increase customer satisfaction. For Partridge (2011, March), "Any supply chain is only as strong as its weakest link. A company can move a product from China to the United States, clear it through Customs, move

it to a distribution center, and fulfill it in record time. But if it doesn't deliver the product to consumers quickly enough, they are not happy, and the company's supply chain has failed."
In a case study by Ylimaula and Ulkuniemi (2013) on a telecommunication company, they found out that social media was used by employees on a minimal level. Some employees did not even know they were using social media. Even though some admitted to the use of social media tools such Skype and LinkedIn to communicate with suppliers, they were oblivious to the idea that it was social media that was been incorporated in their strategy probably because it is a relatively new concept. Previous studies (Rapp et al., 2013; Brin, 2011; Ylimaula and Ulkuniemi, 2013) show that social media use increases customer loyalty and satisfaction. Brown (2016) emphasizes the importance of supply management because it determines if a company retains or loses its customers. Barve (2011) talks about market instability and that speed and flexibility from suppliers is essential for companies to keep abreast and respond to the unique and changing needs of customers. As earlier stated, social media allows companies to engage consistently with its customers; consequently, they remain well informed about their changing tastes and needs. Namely, this constant engagement with customer enables the firms to remain competitive and allows them to relay this information to suppliers promptly to keep customers satisfied. Thus, considering all arguments above, we propose the following hypothesis. In addition, the conceptualized research model of this study is demonstrated below in Figure 1.
H2: *Social media positively moderates the relationship between SRM and customer satisfaction*

Figure 1: Research Model



RESEARCH METHODOLOGY

Sample

Based on the study of Dillman et al. (2014), we design our survey. The data for this study will be collected by sending out surveys to managers of service companies in the United States. The reason for using these respondents is based on previous research (Ghobadian et al., 1994; Akbaba, 2006). These studies show the importance of service quality to the survival of any firm in today's competitive environment. Berry et al. (1989) show that service quality increases employee

and customer satisfaction, reduces cost, and increases business performance. Survey respondents will be offered a summary of the research results from this study in return for responding to the surveys. The responses will be collected over an eight-week period and reminders will be sent out bi-weekly. A sample size of 200 companies will be adequate for this research.

Measures

All measurement items used in this research will be adopted from previous research studies. The scale items will be slightly modified to capture the data needed to carry out this research. The responses are rated on a 7-point Likert scale, anchored by 1 being "strongly disagree" and 7 being "strongly agree". Specifically, social media-related items are adopted from Trainor et al. (2014). Respondents will be asked if they use any form of social media to sell their products/services or use it as way of keeping in touch with their customers. If they respond by clicking “YES”, they will proceed to the corresponding social media questions. Scales developed by Reinartz et al. (2004) will be used to assess CRM usage in the company. These measures include how the company uses CRM to initiate, acquire, and maintain customer information to better respond customer needs and expectations. Scales developed by Swink et al. (2005) will be used to measure SRM. Their measure captures cost, technology, and long-term relationships with suppliers. To measure customer satisfaction, scales developed by (Samson and Tezriovski, 1999; Das et al., 2000; Zu, 2009, Cho et al., 2017) will be adopted. These measure items were slightly revised to suit our research purpose. All scale items used in this study are found in the Appendix

DATA ANALYSIS

Testing of Scale Reliability and Validity

- Scale Reliability is the extent to which an observed variable is consistent, measures the true value of what it is supposed to measure and is error free (Hair et al., 1998 p. 9 and 92). Scale validity is the extent to which the test measures gauge what it is supposed to (Brown, 1996). The Cronbach alpha coefficients will be computed to test the reliabilities of the scales (Powell, 1995). Typically, the coefficients should fall within a range of 0.70 to 0.90 for narrow constructs, and 0.55 to 0.70 for moderately broad constructs (Van de Ven and Ferry, 1979; Powell, 1995).

- Construct Validity is the extent to which the sample accurately represents the objectives or stipulations of the study (Brown, 2000). With construct validity, the researcher’s goal is to analyze the instrument chosen and to make sure it catches the latent variable (Zaiţ and Bertea, 2011, p. 217). To test if there is a relationship between the variables, we use Confirmatory Factor Analysis (CFA) which is “a statistical tool that verifies the factor structure of the observed variables and checks if there is a correlation between the observed variables and the latent constructs” (Suhr, 2006, p. 1).

- Convergent Validity is used to test whether “the scale is measuring the intended concept” (Hair et al., 1998, p.125). To analyze convergent validity, we will use Average Variance Extracted (AVE) (Fornell and Larcker, 1981). AVE is “average variance shared between a given construct and its indicators” (Dean et al. 2008, p.11). If the value of AVE is bigger than

the construct's correlation of other constructs, we assume that convergent validity is confirmed (Gefen et al., 2000; Alumran et al. 2014)

- Discriminant Validity is used to test whether the scales are sufficiently different from each other (Hair et al., 1998). One way to test discriminant validity is to carry out a Chi-square difference test (Segars, 1997). Here, we will collate two models, one of which is correlated and the other which is not. If the statistical test is significant, then we will condluce that there is discriminant validity (Zaiţ and Bertea, 2011).

Testing of Common Method Variance

Since data for this study will be collected using the survey method, and the data from respondents is self-reported, common method variance (CMV) is a major concern (Chang et al., 2010). CMV is ''variance that is attributable to the measurement method rather than to the constructs the measures represent'' (Podsakoff et al., 2003, p. 879). CMV can cause a researcher to make erroneous conclusions about the association between variables either by inflating or deflating the research findings (Craighead et al., 2011). To test if CMA augments the relationships between the variables, we will employ Harman's single factor test with CFA (Harman 1976; Jansen et al., 2005).

Testing of Non-Response Bias

Non-response error is the error that "occurs when a significant number people in a survey sample do not respond to the questionnaire and are different from those who do in a way that is important to the study" (Salant and Dillman, 1994, p. 20). Miller and Smith (1983) emphasize the importance of paying attention to non-response error and suggest that even though the response rate received from a questionnaire is high, non-response error still needs to be considered because certain important information may be missing from the questionnaire, all of which may affect the validity of the study. Non-response error can be assessed by comparing the early and late respondents (Armstrong and Overton, 1977; Hausman and Siekpe, 2009). This is referred to as 'wave analysis'. Respondents who completed and returned their survey before the first deadline are compared to those who returned theirs later (Halbesleben and Whitman, 2013). To compare these two groups, "a random sample of the non-respondents are selected and the researcher collects data from these subjects. The data collected from the non-respondents is compared to data collected from the respondents. If no difference is found, the data can be pooled and inferences made to the population" (Collier and Bienstock, 2007, p.165)

Hierarchical Regression Analysis

To examine the hypotheses developed in this study, we will conduct a three-step hierarchical regression analysis. This analysis allows us to add a set of independent variables to the regression equation and determine how much contribution these variables makes or adds to the dependent variables (Cohen et al., 2013, p.144). In this case, our interest is to determine whether newly added variables show a significant improvement in R^2 (the proportion of explained variance in DV by the model) and the F-ratio (Kim, 2016). To control for the possibility of variance across the two different industries and firm size, we will enter the type of industry and firm size as a control variable. Particularly, our hypotheses are tested based on the following hierarchical regression model:

$Y = \alpha + \beta1X1 + \beta2X2 + \beta3X3 + \beta4X4 + \beta5X5 + \beta6X3X5 + \beta7X4X5 + \varepsilon$ where Y = customer satisfaction, X1 = industry type, X2 = company size, X3 = customer relationship management (CRM), X4 = supplier relationship management (SRM), X5 = social media (SM), and ε = random disturbance terms.

Step 1: Y = Intercept + Industry type + company size

Step 2: Y = Intercept + Industry type + company size + CRM + SRM + SM

Step 3: Y = Intercept + industry type + company size + CRM + SRM + SM + CRM*SM + SRM*SM

DISCUSSION AND CONCLUSION

Theoretical Implication

The study would investigate social media use by analyzing the use of social media in 200 service firms in the United States. The social networking perspective (Scott,1988) provide a basis for which this study is designed and that when resources are effectively used in conjunction with nascent technology can increase customer satisfaction. This study also provides a better insight into the how organizations use social media to improve customer satisfaction, identifies the various forms and ways social media is used in companies. Hence, the results of this study can serve as a guide for other organizations and top management teams who have not incorporate social media in their organization (Trainor et al., 2014; Parveen et al., 2015).

This study suggests that SRM and CRM make a synergic effect with social media on a firm's competitive advantages. This finding is also consistent with the information system literature that indicates using technology alone is not be enough to gain competitive advantage. Instead, our study supports that the use of social media facilitates other organizational capabilities that allow companies better understand their customers and meet their needs (Trainor et al., 2014)

Managerial Implication

The evidence from previous research shows that CRM and SRM have positive effects on customer satisfaction. However, our study suggests that the effects can be significantly improved by incorporating other nascent technology like social media. This is beneficial not only to the company because it increases revenue but it also increases customer satisfaction. Further, this study presents that using social media allows companies to better serve their customers by affording them the opportunity to respond quickly to customer needs and get feedback concerning a product or service. Therefore, managers should consider investing in social media technology and integrate it with other existing systems to enhance their company's capabilities and increase customer satisfaction. However, it is also important to note that there are many regulatory and legal risk associated with using social media (Moorcroft, 2008; Parveen et al., 2015).

Limitation and Future Research

It is well known that retaining a firm's current client base is more profitable than developing new relationships. An understanding of a firm's customers can help companies better tailor their products to maximize customer satisfaction (Chen and Popovich, 2003). However, managing customer relationship is difficult especially in today's dynamic and competitive environment. Even though this study is diverse, the relationships may be less applicable to specific industries that may not see much potential or whose customer demand for social media use is minute (Trainor et al., 2014). Future research can also look at the position of the firm in the industry and if using social media is necessary.

APPENDIX: Survey Measure Items

Social Media Scale Items (Trainor et al., 2014)
Does your organization use any form of Social Media? YES □ NO □
If yes, which of the following represents the reason why you use social media technology**.** Please check all that apply *Conversation support*

□ Blogging (e.g. Blogger, Wordpress, TypePad)
□ Instant messaging (e.g. Google Instant Messenger, MSN, Yahoo)
□ Micro-blogging (e.g. Twitter, Tumblr)
□ Online conferencing/webinar (e.g. Adobe Connect, Go-to-Meeting, Yugma)
□ Live interactive Broadcasting (e.g. UStream.tv)

In this company, we use social media for
Information generation

- We use social media to conduct market research.
- We use social media to detect changes in our customers' product preferences.
- We use social media to detect fundamental shifts in our industry (e.g., competition).

Responsiveness

- We use social media to respond to our competitor's price changes.
- We pay attention to changes in our customers' products or service needs using social media.
- If a major competitor launched an intensive campaign targeting our customers, we would respond immediately using social media.
- The social media activities of the different departments are well coordinated.
- Customer complaints can be filed and tracked using social media in our firm.
- When our customers want us to modify a product or service, we announce that change using social media.

CRM Scale Items (Reinartz et al., 2004)
Technology

- We invest in technology to acquire and manage "real time" customer information and feedback.
- Relative to our competitors the quality of our information technology resources is larger

Initiation

- We have a formal system for identifying potential customers
- We have a systematic process for assessing the value of past customers with whom we no longer have a relationship.

Acquisition

With regard to your SBU, to what extent do you agree to the following statements?

- We made attempts to attract prospects in order to coordinate messages across media channels.
- We have a formal system in place that differentiates targeting of our communications based on the prospect's value.

Maintaining

- We have a formal system for determining which of our current customers are of the highest value.
- We continuously track customer information in order to assess customer value

SRM Measures (Swink et al., 2005)

- We provide technological assistance to suppliers.
- We share our cost information with our major suppliers.
- We require cost information sharing by our suppliers.
- We establish long-term contracts with suppliers.
- We pursue joint investments with suppliers.

Customer Satisfaction measures

- Customer retention about our products and services has increased over the past three years (Das et al., 2000)
- Customer satisfaction about our products and services has increased over the past three years (Zu, 2009; Cho et al., 2017)
- Customer satisfaction with the quality of our products and services has increased over the past three years (Zu, 2009)
- Please choose among one of the followings as the best description of your company's customer satisfaction level (Samson and Tezriovski, 1999; Cho et al., 2017).

(1)	(2)	(3)	(4)	(5)	(6)	(7)
Never meets expectations	Sometimes meets expectations	Often meets expectations	Generally meets expectations	Consistently meets expectations	Always meets expectations	Exceeds expectations

ABSTRACT

Drawing on social network and capabilities theories, this study examines how supplier participation in new green product development influences a manufacturing firm's new green product creativity. The results from a longitudinal survey of 328 manufacturing firms and their suppliers reveal that novel green knowledge sharing mediates the effect of supplier participation on manufacturing firms' new green product creativity. In particular, the effect of supplier participation on novel green knowledge sharing is enhanced by knowledge sharing capability, while the effect of novel green knowledge sharing on new green product creativity is enhanced by joint learning capability.

KEYWORDS: Supplier participation, Manufacturing firm, Green innovation

INTRODUCTION

Manufacturers intending to adopt green innovation often proactively involve suppliers in their new green product development (NGPD) process (Govindan et al., 2015). The existing literature has also acknowledged the benefit of engaging suppliers in the NGPD process (e.g., Chatterjee et al., 2018; Katsikeas et al., 2016; Dou et al., 2014). While existing studies provide rich insights into how suppliers can contribute to a manufacturer's green product innovation, the results of studies in this research stream are mixed.

Some studies find a strong relationship between supplier participation in NGPD (hereinafter 'supplier participation') and NGPD performance. That is, manufacturers with effective supplier participation will perform better than those that do not adopt supplier participation (e.g., Chatterjee et al., 2018; Katsikeas et al., 2016; Dou et al., 2014). Conversely, other studies report lower or even no significant correlations between supplier participation and NGPD-related performance (e.g., Kumar et al., 2016; Leonidou et al., 2013; Azevedo et al., 2011). Kumar et al. (2016) report that short run green adoption is a costly process for NGPD. Leonidou et al. (2013) find that managers are expected to perceive greening efforts as risky for NGPD performance. Azevedo et al. (2011) reveal that green practices have negative effects on the performance of supplier involvement.

Most studies attribute these inconsistencies to factors that potentially influence the supplier participation–NGPD performance relationship, such that the time necessary to understand the knowledge of the green supplier may be too costly (Blome et al., 2014), involving suppliers in NGPD may lead to deterioration of manufacturing firm NPD capabilities (Huo et al., 2018), and manufacturing firm employees may reject suppliers' knowledge (Dou et al., 2014). Although supplier participation has been identified in the literature as a key driver of manufacturer green

innovation, the process through which it affects manufacturers' NGPD is apparently still not well understood.

The primary objective of the present study, therefore, is to explain why some manufacturing firms are more successful than others in converting their supplier participation into superior NGPD performance. Building on social network theory (Burt, 1997), we examine the role of supplier participation on the manufacturers' new green product creativity. Based on previous work of Moorman and Miner (1997), Dean et al. (2016), and Dayan et al. (2017), new green product creativity refers to the degree to which a new green product is perceived to provide unique and meaningful differences to manufacturers' customers. Since new product creativity is a necessary condition for successful innovation, by providing meaningful differences from rivals, creativity leads to product differentiation and competitive advantage for manufacturers (Dayan et al., 2017). However, while supplier participation has a potential value for manufacturer innovation, the actual impact is achieved when the manufacturing firm can detect and assimilate information from its suppliers. Because suppliers' knowledge is implicit in nature (Luzzini et al., 2015), knowledge sharing between the manufacturing firm and its supplier reflects a key relational process for successful knowledge assimilation (Gao et al., 2015). Therefore, extending previous research, we propose novel green knowledge sharing as a critical process through which supplier participation affects manufacturer new green product creativity.

Furthermore, according to capabilities theory (Eisenhardt and Martin, 2000; Teece, 2014) and relevant studies (e.g., Dai et al., 2017; Handfield et al., 2015; Menguc et al., 2014), an important driver of a manufacturing firm's ability to translate supplier participation into superior NPD performance is its organizational capabilities. This proposition is based on the premise that how supplier participation is deployed to capture, share, and exploit novel knowledge resources amid competitive pressures, and the quality of deployment of supplier participation, will depend on the strength of a manufacturing firm's organizational capabilities (Kozlenkova et al., 2014). Accordingly, drawing on capabilities theory, we propose two green organizational capabilities that help with deployment of supplier participation: knowledge sharing capability and joint learning capability. Knowledge sharing capability refers to a manufacturing firm's ability to develop mechanisms that promote the exchange of novel green knowledge among suppliers participating in NGPD activities (Cai et al., 2010). Joint learning capability refers to a manufacturing firm's ability to learn collectively with its suppliers in creating green innovation value through novel green knowledge for both parties during the NGPD process (Fang and Zou, 2010; Foss et al., 2010).

HYPOTHESES

In this study, supplier participation is defined as the extent to which manufacturers incorporate their suppliers into NGPD and continuously improve new product projects (Yan et al., 2018). Specifically, supplier participation includes both the breadth and depth of supplier participation in the NGPD process. Breadth captures the scope of participation across the NGPD process, while depth represents the green supplier level of participation in a stage of the NGPD process.

Researchers have proposed that supplier participation affects a manufacturer's NGPD process by increasing the level of knowledge shared during the NGPD process, and by improving how well two firms coordinate their actions during the NGPD process (Albort-Morant et al., 2018). Novel green knowledge sharing refers to the extent of the exchange of novel green knowledge about the green product idea, market, and competition, among other issues, during the NGPD process that facilitates inter-firm collaboration among supply chain members (Li et al., 2014). This implies that supplier participation enhances the ability of both manufacturers and suppliers to identify what knowledge needs to be shared and how to work more cooperatively.

When a green supplier participates in a manufacturer's NGPD process, each party knows the pertinent green knowledge possessed by the other, which helps them evaluate and recognize what knowledge to share, and increases the efficiency of their coordination effort (Jean et al., 2014). Researchers have also found that suppliers' early participation in the NGPD process and higher levels of social interaction between the parties improve the knowledge intensity, frequency, and breadth (Katsikeas et al., 2016).

While most research argues for the positive effects of supplier participation on NGPD performance (e.g., Dai et al., 2017; Govindan et al., 2015; Lee and Kim, 2011), it is possible that, if the interaction is dysfunctional or leads to conflict, higher levels of participation could be detrimental and offset some of the expected benefits. Therefore, we expect that higher levels of supplier participation improve communication and help both the suppliers and manufacturers specify the behaviors desirable in the relationship, which enhances the effectiveness of novel green knowledge sharing. Thus, we hypothesize that:

H1: Supplier participation positively affects novel green knowledge sharing.

Jean et al. (2010) have identified communication between the supplier and manufacturer regarding manufacturers' new product preferences as a key prerequisite for new product creation. Research on the formation of manufacturers' new product preferences suggests that these preferences and needs evolve through supplier participation in specific new product ideas, concepts, and prototypes across the NPD stages (Yeniyurt et al., 2014). As such, constant novel green knowledge sharing should help suppliers probe and learn how manufacturer needs evolve and emerge during the NGPD process. Moreover, novel knowledge shared by the supplier with the manufacturer about cost structure and production and engineering options helps manufacturers realize constraints and, thereby, make appropriate adjustments in their preferences for NPD (Yang et al., 2016). Following this line of reasoning, due to novel green knowledge sharing, manufacturers and suppliers should be better able to discover unique opportunities for new green product creativity.

In particular, green innovation requires the manufacturing firm to assimilate and recombine novel knowledge perspectives from various sources (Behnam et al., 2018). Supplier participation exposes the manufacturing firm to dissimilar green knowledge, which increases the number and variety of potential combinations and novel solutions (Watson et al., 2018). In addition, exposure to diverse green knowledge and perspectives also stimulates the manufacturing firm to blend different knowledge elements, which represents a key cognitive process for generating novel insights (He et al., 2018). Further, supplier participation can stimulate the manufacturing firm to develop flexible, outside-the-box thinking. As a result, because supplier participation offers the manufacturing firm an approach to observe how a problem could be solved differently, it challenges the manufacturing firm's existing cognitive structures, including its premises and beliefs about cause-and-effect relationships (Behnam et al., 2018). The manufacturing firm, thus, is more likely to develop multiple conceptualizations of problems and find novel solutions.

At the same time, supplier participation can provide the manufacturing firm with brokerage advantages through rich connections (Potter and Lawson, 2013). In such connections, the manufacturing firm can observe and access diverse expertise, perspectives, and knowledge in various fields. In turn, novel green knowledge can be applied, modified, and experimented with in new areas and then achieve green innovative outputs (He et al., 2018). As Gao et al. (2015) find, suppliers embedded in supply chain networks with high levels of knowledge heterogeneity are good sources of creative ideas. Accordingly, in the NGPD process, novel green knowledge sharing between suppliers and manufacturers should increase the level of manufacturers' new green product creativity. Thus, we hypothesize that:

H2: New green product creativity is positively affected by novel green knowledge sharing.

While supplier participation likely stimulates manufacturer green innovation, little is known about the underlying process linking supplier participation and manufacturer new green product creativity. We propose that novel green knowledge sharing is a critical relational process that mediates the effect of supplier participation on manufacturer new green product creativity.

The knowledge-based view argues that suppliers are a key element in creating new knowledge, but if this knowledge is not shared with other supply chain members, it will have very little impact on the performance of the supply chain network (Grant, 1996; Handfield et al., 2015). Thus, when the green knowledge possessed by the suppliers is shared and transferred from one to another within a supply chain network, synergy occurs (Ghali et al., 2016). Especially, supplier participation typically performs project-based work of a non-routine and complex nature, so such work requires effective coordination and the integration of novel knowledge (Lee, 2015). In addition, in order to take advantage of each party's individual competencies, suppliers and manufacturers must coordinate their efforts to increase the effectiveness of their novel green knowledge sharing across the different stages in the NGPD process (Pinheiro et al., 2018). The novel green knowledge sharing will, thus, play a key role in manufacturing firms' NGPD process.

However, it is also vital that the novel knowledge is shared in order for innovation to be created (Gao et al., 2015). Suppliers can have diverse and novel knowledge, but the manufacturer may not necessarily benefit from such diversity automatically if the suppliers are unwilling to proactively share their proprietary knowledge. Similarly, in supplier participation where multiple suppliers are involved, competition for the manufacturer's NGPD can stimulate proactive green knowledge sharing from suppliers. In addition, frequent knowledge sharing keeps the manufacturer updated with novel knowledge so that it can detect critical knowledge more easily (Jean et al., 2014). Moreover, knowledge sharing through formal and informal mechanisms, including routine interactions, frequent meetings, and impromptu and random encounters, enhances the manufacturers' ability to assimilate suppliers' knowledge (Yeniyurt et al., 2014). Most importantly, because technological knowledge provided by suppliers is difficult to codify and communicate, effective knowledge sharing between the manufacturer and the suppliers is critical for the manufacturer to fully understand and successfully integrate the acquired knowledge (Martín-de Castro, 2015).

Overall, it is predictable that supplier participation will be more effective when there is effective novel green knowledge sharing between the manufacturer and its suppliers. Based on this assumption, we propose the following hypothesis:

H3: Green novel knowledge sharing mediates the relationship between supplier participation and new green product creativity.

Knowledge sharing capability is a commercial prerequisite for business-network-based structures and is essential in obtaining and processing information and identifying opportunities in these structures (Cavaliere et al., 2015). It can be conceptually disaggregated into a firm's capacity for: knowledge dissemination, distribution, contribution, and transfer. Thus, knowledge sharing capability is an important capability in enhancing organizational innovation performance (Brandon-Jones et al., 2014). As such, we propose that developing knowledge sharing capability should enhance the impact of supplier participation on novel green knowledge sharing for the following reasons.

First, firms with strong knowledge sharing capability can effectively transfer knowledge, so that the recipient of that knowledge can understand it well enough to act on it (Zhou and Li,

2012). Knowledge sharing capability enables firms to increase their understanding of an underserved new knowledge base (Ho and Ganesan, 2013). Such knowledge is the main prerequisite for outcomes related to green innovation (Albort-Morant et al., 2018). Thus, knowledge sharing capability improves manufacturing firms' innovation potential through quicker access to, and processing of, novel green knowledge.

Second, knowledge sharing capability facilitates the achievement of supplier participation and innovation goals through external coordination of a firm's novel knowledge (Jean et al., 2014). This capability to bring supplier participation and new knowledge together and, subsequently, to share such knowledge internally, is likely to improve the quality of novel knowledge sharing (Gao et al., 2015). Thus, strong knowledge sharing capability complements supplier participation and, at the same time, reduces inefficient or excessive knowledge resource allocation.

Third, knowledge sharing capability is considered an enabler in which one unit is affected by the knowledge and expertise of another unit (Lahiri, 2010). In addition, it considers the extent to which such units use and build on each other's knowledge an important part of knowledge sharing which may occur through formal collaboration or in informal everyday interaction. Furthermore, firms with strong knowledge sharing capability can maximize organizational capacity to encourage their external participants to share their novel and unique knowledge, which will help the firms gain a competitive advantage (Foss et al., 2010).

Accordingly, based on the above reasoning, it is logical to assume that, when a manufacturing firm has strong knowledge sharing capability, their outcomes of supplier participation are strengthened, while novel green knowledge sharing is enhanced. Thus, we hypothesize that:

H4: Knowledge sharing capability positively moderates the effect of supplier participation on novel green knowledge sharing, such that the effect is stronger at a higher level of knowledge sharing capability.

Joint learning capability reflects a relational capability that captures the degree of partner cooperation and participation in developing a relationship-specific, inter-organizational process and communication channel aimed at creating and integrating knowledge for value creating (Huikkola et al., 2013). Although supplier participation, enabled by knowledge sharing capability, may generate new green product creativity through novel green knowledge sharing, that creativity must be captured by joint learning (Jean et al., 2016). Although some managers may assume that novel knowledge sharing in itself leads to successful innovation, a recent study by Wang, Noe, and Wang (2014) shows only moderate support for such a relationship, a finding that could be explained by differences in firms' specialized capabilities.

The role of joint learning capability helps firms create new knowledge sets and transform relational ties into better outcomes (Fang and Zou, 2010; Foss et al., 2010). Strong joint learning capability provides two primary advantages. First, innovation generation is a process of knowledge exchange and combination (Grant, 1996). Joint learning capability involves a firm's exchange of different knowledge resources with its partners to exploit complementarities. With the help of knowledge exchange through joint learning capability in novel knowledge sharing, firms are able to refine and extend their existing product innovation knowledge, which consequently triggers more novel ideas (Jean et al., 2014). Second, strong joint learning capability cultivates goodwill-based trust, such that firms rely on the intentions and behaviors of partners in a specific relationship (Beske et al., 2014). The strong joint learning capability, thus, facilitates collaboration among partners.

We posit that strong joint learning capability helps the manufacturing firm enhance the value of novel green knowledge sharing in generating new green product creativity. First,

goodwill-based trust from strong joint learning capability could help the firm overcome difficulties associated with diverse knowledge assimilation and recombination. Sharing exclusive knowledge with partners is inherently risky, because the offering firm could lose its core proprietary assets if the receiving firm behaves opportunistically (Zhou et al., 2014). Trust in strong joint learning capability can enhance suppliers' confidence that the manufacturing firm will not exploit its vulnerabilities (Jean et al., 2014). Therefore, suppliers are more willing to share novel green knowledge with manufacturing firms.

Second, by facilitating implicit knowledge sharing, strong joint learning capability enhances the value of new product creativity for manufacturers' NGPD. Although supplier participation provides novel and unique knowledge, the knowledge is usually complex and implicit, and difficult to assimilate and utilize (Handfield et al., 2015). Because strong joint learning capability enables the partners to learn about each other's NPD and develop mutual knowledge (Jean et al., 2014), this improves the manufacturer's capacity to absorb complex and implicit knowledge from suppliers. Thus, the manufacturer is more likely to explore with various combinations of diversified and novel green knowledge, leading to greater levels of new green product creativity.

Conversely, if a manufacturing firm does not possess adequate joint learning capability its innovation strategies may be weak, hampering its ability to extract novel knowledge from the supplier. As such, manufacturing firms with weak joint learning capability will face challenges in generating new green product creativity that is the potential value hidden in green innovation. Therefore, we hypothesize that:

H5: Joint learning capability positively moderates the effect of novel green knowledge sharing on new green product creativity, such that the effect is stronger at a higher level of joint learning capability.

RESEARCH METHODS

Consistent with previous studies on green innovation (e.g., Cheng et al., 2014; Shang et al., 2010), this research chose manufacturing industries in Taiwan as the research setting. Among the 328 manufacturing firms, average annual sales revenue was $7.2 million US. The average number of employees was 1168. These respondents had a mean industry experience of 11.2 years and a mean firm experience of 9.6 years. The firms in the sample were distributed by sector, as follows: 66 firms were general machinery (20.1%), 63 firms came from electrical and electronic machinery (19.2%), 58 firms were transportation equipment (17.7%), 51 firms were automobiles (15.5%), 46 firms represented plastics (14.1%), 39 firms were pharmaceuticals (11.9%), and 5 firms were in other sectors (1.5%).

DATA ANALYSIS AND RESUTS

For the model estimation, we used average scores across the items of the constructs, mean-centered to increase interpretability and minimize nonessential multi-collinearity (Aiken and West, 1991). Using Mplus (Muthén and Muthén, 2012), estimates show that the effect of supplier participation on novel green knowledge sharing is positive and significant (0.231, $p < 0.01$), and the effect of novel green knowledge sharing on new green product creativity is positive and significant (0.248, $p < 0.01$), supporting H1 and H2, respectively.

We ran an additional model to check for mediation. We excluded both the interaction terms "supplier participation × knowledge sharing capability" and "novel green knowledge sharing × joint learning capability" for the mediation-only model and ran a Bayesian mediation analysis. The indirect effect is significant (supporting H3), while the direct effect is insignificant supporting mediation, or indirect-only mediation, following Zhao et al. (2010).

The interaction term supplier participation × knowledge sharing capability, is positive and significant (0.253, $p < 0.01$), thus supporting H4. The interaction effect of novel green knowledge sharing and joint learning capability is significant and positive (0.267, $p < 0.01$), in support of H5.

DISCUSSION AND CONCLUSIONS

The findings provide several important contributions to existing green manufacturing research. We develop a more comprehensive theoretical model of how manufacturing firms benefit from supplier participation through the process of novel green knowledge sharing. Although researchers have long recognized the importance of suppliers for manufacturer green innovation (Chatterjee et al., 2018; Katsikeas et al., 2016; Dou et al., 2014), few studies have examined the underlying processes for the efficacy of supplier participation from the perspectives of social network and organizational capabilities. Thus, it is critical to examine the underlying mechanism through which supplier participation contributes to manufacturer green product innovation. While supplier participation provides manufacturing firms with access to external and rich green knowledge, its potential value must be achieved using the process through which the manufacturers and suppliers interact and share the novel green knowledge. That is, novel green knowledge sharing mediates the effect of supplier participation on manufacturer new green product creativity. Therefore, manufacturing firms may not necessarily benefit automatically from supplier participation, without suppliers being willing to proactively share the novel green knowledge. Extending previous studies that emphasize the direct benefit of relational embeddedness between manufacturers and suppliers (Gao et al., 2015; Zhou et al., 2014; Day et al., 2013), our findings provide new evidence that novel green knowledge sharing, from a perspective of relational embeddedness, acts as a mediator for manufacturing firms to benefit from supplier participation.

Our findings provide important implications for manufacturing firms to leverage their supplier participation to facilitate NGPD performance. Our findings suggest that the impact of supplier participation on new green product creativity is maximized at higher levels of knowledge sharing and joint learning capabilities. Managers, therefore, need to ensure that resources are allocated to building knowledge sharing and joint learning capabilities when employing supplier participation. Particularly, the results hint at some unintended consequences of low-level joint learning capabilities. At lower levels of joint learning capability, supplier participation has a negative impact on new green product creativity. This result gives pause to the finding of Govindan et al. (2015) that the impact of supplier participation on green innovation performance is strong and positive. Our results show that this may not be the case for all firms, particularly those at the lower end of the continuum in their green organizational capabilities. Overall, these results call for manufacturing firms to focus on supplier participation, but with recognition of the limits of such a focus and an appreciation for the increased success they can achieve if they simultaneously build essential green organizational capabilities.

The results of this study must be viewed in light of its limitations. First, because supplier participation and both knowledge sharing and joint learning capabilities were captured from a survey, there could potentially be a positive or upward bias on these measures. Future research can consider exploring secondary sources for capturing these metrics.

Second, while this study took a supply-side view to focus on new green product creativity generated by the manufacturing firm, examining the demand-side view of the value of green innovation may also be interesting and valid. Future studies could also take a comprehensive view of customer participation and link it to demand-side concepts, such as customer value.

DECISION SCIENCES INSTITUTE

The Use of a Self-Managed Learning Project to Teach Governmental Accounting Topics

ABSTRACT

A self-managed learning project was investigated that required the students to actively participate in their learning by organizing information and writing on moderately complex governmental accounting topics (general capital assets and capital projects funds). The short and long-term project effects were assessed. The student perceptions of the benefits of the project in (a) understanding the topics, (b) doing the homework, and (c) preparing for a quiz/exam were examined by obtaining opinions from student surveys. The self-managed learning project was effective in learning selected governmental accounting topics and it appears to be a good alternative teaching method.

KEYWORDS: Self-managed learning, Governmental accounting, Alternative teaching method

INTRODUCTION

Accounting committees over several decades have recommended that the accounting curriculum should be revised. The Pathways Commission (2012) accelerated the discussion when they indicated that the responsibilities of accounting educators should include both curricular dimension (what we teach) and pedagogical scope (how we teach). Under pedagogical scope this committee suggested that approaches or learning experiences should be developed to help students in thinking, performing, and making decisions that are comparable to accounting professionals.

Earlier, Albrecht and Sack (2000) emphasized that accounting educators need to assist students to improve their ability-to-learn skills. The self-managed learning project (self-generated elaboration) used in this research should give students an opportunity to cultivate or expand their ability to "learn to learn."

In November 2015, the Pathways Commission suggested that accountants develop a signature pedagogy for learning the "Accounting Common Body of Knowledge" that will support the learning approaches of a diverse student body. In 2013 Apostolou *et. al.*, indicated that accounting research is needed to ascertain the best ways to teach or to learn core professional competencies (e.g., communication skills). The research in this paper involved an investigation of whether a self-managed learning project in a Governmental Accounting course is a good technique for teaching selected governmental topics.

In 2008 Jackson and Durkee emphasized that the instructor's role must switch from being the presenter of facts to facilitator of active learning in order for the students to achieve the necessary professional skills. According to Helliar (2013) teaching techniques that engage students should be an essential component of accounting education (e.g., role playing, self-managed learning, and group activities). One of the characteristics of signature pedagogy stipulated by Schulman (2005, pp. 56-57) includes learning experiences that ensure students are active and interactive. Our self-managed learning project was created to engage the students and to require them to actively participate in their own learning.

The Pathways Commission in August 2014 asserted that quality education should incorporate various teaching methods that would encourage students to develop their ability to exercise professional judgment in decision making. Also, Bandura and Lyons (2012) suggested that instructors should include different learning approaches (e.g., lecture, problem-solving, or self-managed learning) in their courses. In addition, Wessels (2010) maintained that the instructor's fundamental role is to persuade students to embrace learning activities that will probably result in the students achieving the desired learning outcomes for the course. Our research study used a self-managed learning project to assist Governmental Accounting students in understanding the general capital assets (GCA) and the capital projects funds (CPF) topics.

Previously, the Accounting Education Change Commission [AECC] (1990) asserted that accounting students should actively participate in the learning process and not be just passive recipients of information. Earlier, the American Accounting Association (The Bedford Committee) 1986; American Institute of Certified Public Accountants 1988; and "Big 8" (now Big 4) CPA firms ("Perspectives . . .") 1989 all have advocated change in accounting education. These committees consistently advocated that accounting education should place more emphasis on writing skills and critical thinking skills.

The AECC in 1990 stated that the accounting curriculum "should lay the base on which life-long learning can be built." The Quality Assurance Agency for Higher Education (2002) suggested that accounting students should have the capability for independent and self-managed learning. The project utilized in this research introduced the students to self-managed learning.

One of the proposals of the Pathways Commission in 2012 was to develop the accounting body of knowledge (Action Item 4.1.1). In November 2015 the Pathways Commission's Knowledge and Pedagogy Task Force endorsed a "Common Body of Knowledge Learning Objectives" for accounting (e.g., communication). Previously, the AICPA Core Competency Framework for Entry into the Accounting Profession (Framework) (1999) identified a set of essential competencies (encompassing 100 elements) for students preparing to enter the accounting profession (e.g., organize, communicate). These competencies are comparable to the skills set elaborated by educators and practitioners in Albrecht and Sack (2000), Canadian Institute of Chartered Accountants [CICA] (2010), the Institute of Management Accountants (1994), the Institute of Internal Auditors (1999), and the Accounting Education Change Commission [AECC] (1990). Our self-managed learning project (elaboration) was designed to enable the students in a Governmental Accounting course to utilize organizational and written communication skills recommended by the Pathways Commission's learning objectives and the AICPA Framework elements.

Our study contributes to the existing accounting literature by investigating the effects of a self-managed learning project on moderately complex governmental accounting topics. Also, there was further exploration of the effects of this teaching technique on both short-term and long-

term knowledge retention. In addition, student opinions of the self-managed learning technique were obtained and an analysis was conducted.

THEORY

Learning-to-Learn

The Pathways Commission (2014) stated that high-quality accounting education should prepare students for a lifetime of learning. In addition, Albrecht and Sack (2000) implied that accounting educators need to assist students in the development of their ability-to-learn skills. Further, Gammie and Kirkham (2008) indicated that the ability to "learn to learn" is a key competency needed by accountants to adapt to the rapidly changing business environment. Our self-managed-learning project should permit the students to have an opportunity to develop or expand their ability to "learn to learn."

The role of learners according to the constructive learning theory is to actively participate in activities that construct their knowledge base. Under this theory the learning environment should be aligned with learning outcomes, which should foster independent learning. According to Seifried (2012) and Tan and Ferreira (2012), constructive alignment transpires when learning outcomes, teaching and learning activities, and assessment are carefully coordinated. Students need to "learn to learn" so that in their professional careers they will be able to discover needed tacit knowledge. Our self-managed learning project enabled the students to participate in an activity that should help them construct their knowledge base.

Other cognitive researchers (Anderson 1970; Gage and Berliner 1984; Ross 1983; and Glaser 1984) have implied that learning is an active process, which involves several steps. The first step requires the students to be attentive. Secondly, the students must encode the information into their own words in a meaningful way. Finally, the students must relate the new information with their previously learned related knowledge.

The self-managed learning concept is similar to the "discovery learning" method (Davidson 1990). Davidson found that the learners were able to retain more because they had discovered the knowledge themselves. Accounting researchers (Springer and Borthick 2007; Hermanson 1994; and Cottell and Millis 1993) have found that when the learners generate their own solutions and/or explanations, they experience ownership and are more likely to retain the information. Our project required the students to develop their own explanations thus allowing them to experience ownership of the information generated during preparation of the project, which should help them retain the knowledge acquired.

Elaborations

Annis (1985) suggested that student-generated paragraph summaries seem to help the students in executing the vital encoding process more efficiently than either note-taking or only reading the information. Levin [1988] found that the learning process might be enhanced by utilizing elaborations. Anderson [1983] defined an elaboration as any information that explains or clarifies some to-be-learned (target) information. An elaboration can be thought of as the link that allows the new target information to be integrated into the student's present knowledge. In addition, several cognitive research studies (e.g., Anderson [1983], Stein *et al.* [1984] and Reder *et al.* [1986]) suggested that elaborations can facilitate memory. Types of elaborations include summaries, examples, analogies, and self-explanations.

Past research has indicated that student-generated paragraph summaries tend to be generally superior to externally presented information (Hite and Parry 1994; Schadewald and Limberg 1990; Pressley *et al.* 1987; Jacoby 1978; Slamecka and Graf 1978; and McFarland, Jr., *et al.* 1980). Bransford *et al.* (1982) found that self-explanations tend to facilitate memory because self-generated elaborations assist the memory to reconstruct the target information, which permits later recall. These research studies involved the encoding of topics that were relatively basic or not very complicated. In contrast, our study involved moderately complex governmental accounting topics. The preparation of the project should help the students retain the knowledge acquired. In addition, the students in our study completed a survey to determine their opinions of the usefulness of the project in (1) understanding the topics, (2) doing the homework, and (3) preparing for a quiz and an exam.

Complexity

Various researchers [Anderson (1995), Driscoll (1994), Gagné and Medsker (1996), Gredler (1997), and Schunk (1996)] have suggested that instructors need to establish different learning opportunities to accomplish different types of learning objectives. Boh *et al*. (2001) indicated that lecture-based training may not be an adequate transfer technique when complexity of knowledge is high.

Bonner (1999, p. 11) suggested that "learning objectives involving complex skills require teaching methods that promote active learning on the part of the students, while learning objectives involving simpler skills can be achieved with more passive teaching methods." In our research the students were required to organize moderately complex governmental accounting topics using a self-managed learning elaboration technique.

Writing-to-Learn

The ability of the accounting students to write is important to the profession. As a result, various professional committees over many years have consistently advocated that accounting education should place more emphasis on writing skills and critical thinking skills. More recently, both the Pathways Commission (2015) and the AICPA's Framework (1999) have indicated that beginning accounting professionals should be able to organize and effectively communicate information so that it can be readily understood by the receiving party.

Hite (2001) recommended incorporating writing exercises into accounting courses when large quantities of information need to be taught (as is the situation in a governmental accounting course). Previously, Stocks *et al.* (1992) commented that writing-to-learn is as important as learning-to-write. In another study, Stout *et al.* (1991) examined the effect of writing assignments on course knowledge. Scofield and Combes (1993) implied that written assignments allow the students to individualize the learning process thus creating their own unique versions of the concept. Zinsser (1988) suggested that writing helps students determine what they do know and do not know.

In 2012 the Pathways Commission suggested that accounting students must possess both technical knowledge and professional skills such as the ability to communicate effectively. In a follow-up report, the Pathways Commission (2014) suggested that quality accounting education should result in students improving their oral and written communication skills. Earlier, Bui and Porter (2010) found in a survey that employers considered communication skills to be essential

for accounting graduates. Despite educators best attempts there still appears to be a disparity between practitioners desired communication skills of accounting graduates and what is possessed by the new graduates according to Conrad and Newberry (2012). Considering this disparity, the Pathways Commission (2015) included under "Professional Foundational Competencies" learning objectives related to communication.

Further, the International Federation of Accountants (IFAC) in its International Education Standard 3 (IES3), Professional Skills and General Education (2008) emphasized that entering accountants should have communications skills. In addition, the Institute of Chartered Accountants in Australia (ICAA) and Certified Practicing Accountants of Australia (CPA Australia) in their International Accreditation Guidelines for Accounting Degree Programs (ICAA/CPA Australia, 2009) indicated that cognitive skills (e.g., writing skills and thinking critically) are essential for accounting graduates to succeed. Our self-managed learning project gave the students an opportunity to write on moderately complex governmental accounting topics.

Learning to Organize

The Pathways Commission's Common Body of Knowledge Learning Objectives (2015) stated that accounting students should be able to identify appropriate accounting information. One of the skills sets that the AECC (1990) believed that students should possess is the ability to locate, obtain, and organize information. In 1999 the AICPA in its Framework (Functional Competencies category under Decision Modeling) indicated the need for entry-level accounting professionals to be able to organize and evaluate information.

Our study presented a self-managed learning technique that required the students to actively participate in the learning process by organizing and writing on information related to selected technical governmental accounting topics. The topics utilized were (1) general capital assets (GCA) and (2) capital projects funds (CPF).

In summary, literature suggests that student self-managed learning can enrich the learning process and that writing projects can be utilized as a learning tool. Since the benefit of self-managed learning techniques may have a greater short-term effect than a long-term effect, the following hypotheses were used to test these effects.

H_1: The distribution of Quiz scores on the GCA (CPF) questions are the same for the students who prepared an outside of class project on this topic as the students who did not prepare an outside project for this topic.

H_2: The distribution of Exam II scores on the GCA (CPF) questions are the same for the students who prepared an outside of class project on this topic as the students who did not prepare an outside project for this topic.

Learning from Examples

VanLehn (1996) suggested that learning from worked-out examples is a good source of learning. Thus, working-out (i.e., reviewing) examples in a governmental accounting textbook should be an important source of learning. According to Anzai and Simon (1979) and Sweller and Cooper (1985), it is possible to learn from working-out examples.

In fact, Anderson, *et.al.* (1984) and Recker and Pirolli (1995) indicated that the preferred learning mode of novices is to work-out examples. Zhu and Simon (1987) noted that learning is achieved more quickly using worked-out examples than from lecturing if the examples are appropriate. They also indicated that participants using the worked-out examples acquired not just rote learning but an in-depth understanding of the subject(s). Other cognitive researchers [Anderson (1987), Tarmizi and Sweller (1988), and Ward and Sweller (1990)] have shown that the utilization of worked-out examples is normally a very effective method of learning.

The students in our research study were required to complete a questionnaire to determine their opinions of the usefulness of reviewing the textbook examples related to the general capital assets (GCA) topic and the capital projects funds (CPF) topic in (1) understanding these topics, (2) preparing the homework, and (3) studying for a quiz/exam on these topics. In addition, this research study compared the students' opinions associated with reviewing textbook examples to reading only the text in the textbook.

Like Stone and Shelly (1997), our study used a questionnaire to measure (Likert-scale used) student perceptions of the self-managed learning technique. The following hypotheses were used to test whether the students considered the project, textbook, and the textbook examples to be useful in understanding the appropriate governmental accounting topics:

H_3: In understanding the GCA (CPF) topics, the students will consider the self-managed learning project (Project) to be as useful as reading the textbook.

H_4: In understanding the GCA (CPF) topics, the students will consider the self-managed learning project (Project) to be as useful as reviewing the textbook examples.

H_5: In understanding the GCA (CPF) topics, the students will consider reviewing the textbook examples to be as useful as only reading the text in the textbook.

Students should be able to apply their newly acquired knowledge. A good self-managed learning project should help the students in this process. The preparation of homework assignments is probably the first time the students apply their recently acquired knowledge. When students take a quiz/exam they also are applying their knowledge. The following hypotheses were used to ascertain if the students believed that the Project was most helpful in (1) understanding the topics, (2) doing homework, or (3) preparing for a quiz/exam:

H_6: The students will consider the Project to be as useful in understanding the GCA (CPF) topics as doing the homework on the topics [preparing for the quiz (exam) on the topics].

H_7: The students will consider the Project to be as useful in preparing for the quiz (exam) on the GCA (CPF) topics as doing the homework on the topics.

RESEARCH METHODS

A governmental accounting class taught by one of the researchers was used in the experiment. At the beginning of the semester, the students were requested to complete a personal data sheet (e.g., classification, university GPA, accounting GPA, credit hours enrolled, work hours, number of accounting course(s) enrolled in during that semester, number of previous

accounting courses, and gender). There were no significant differences between the two experimental groups (GCA topics and CPF topics) on the reported demographic information.

Projects

Every other student in the class was assigned to Group A. In Group A the students were asked to prepare a project (Project A) to assist them in learning about general capital assets (GCA). On the same day, the other students in the class (Group B) were asked to prepare a project (Project B) to assist them in learning about capital projects funds (CPF). The students in both groups were told they could use a checklist, chart, graph, grid, flowchart, outline, or other approach that would help them understand the topics. The project was not to be more than 1 1/2 pages in length. The students were given one week to prepare the project. To encourage the students to complete the project, the project was assigned 25 points, which represented about 4 percent of their grade. The students were instructed to make copies of their projects, which were to be used in preparing their homework assignments related to the topics. On the day that Project A was due, Group B was required to read the GCA topics in the textbook (13 pages). On the day that Project B was due, Group A was required to read the CPF topics in the textbook (17 pages). Both groups received the same class discussion and were assigned the same homework problems for these topics.

Testing

In the class period following the discussion of the homework problems on these topics, a common Quiz was given. During the class period prior to the Quiz, the students were reminded to use their projects to help them study for the Quiz. On this Quiz there were 9 points related to GCA topics and 11 points pertaining to the CPF topics. The results of this Quiz were used to measure the short-term effect of this teaching technique.

Two weeks following the Quiz, a common exam (Exam II) was administered. In the class period before Exam II, the instructor suggested that the students use their projects to help them study for this exam. The results of this exam were used to measure the long-term effect of this teaching technique.

Student Surveys

Just prior to the students receiving the results of the Quiz, the students were requested to complete a survey to determine their opinions on the usefulness of the project in (1) understanding the topics, (2) preparing the homework assignments, and (3) studying for the Quiz. In addition, other questions were included, which were related to the usefulness of both the textbook readings and examples in (1) understanding the topics, (2) preparing the homework assignments and (3) studying for the Quiz.

Prior to returning Exam II, the students were requested to complete another survey to determine their opinions on the usefulness of the project in (1) understanding the topics, (2) preparing the homework assignments, and (3) studying for Exam II. Also, the survey included questions related to the usefulness of both the textbook readings and examples in (1) understanding the topics, (2) preparing the homework assignments and (3) studying for Exam II.

RESULTS

A quiz, which was used to measure the short-term effect of the self-managed learning projects, will be discussed first. Next, the long-term effect (Exam II) will be investigated. Also, the student survey results will be analyzed.

Quiz

During the class period following discussion of the problems on the general capital assets (GCA) and capital projects funds (CPF) topics, a common Quiz was administered, which included 9 points related to the GCA topics and 11 points on the CPF topics. The results of this Quiz were used to measure the short-term effect of the self-managed learning technique. For Project A the students with and without the project scored equally well on the GCA topics (see Table 1). The students with Project B scored slightly higher than the students without the project on the CPF topics, but the chi-square test indicated that the effect of the self-managed learning Project B was not statistically significant.

Table 1
Percentage of Correct Answers by Project Type
Quiz

GCA Project		CPF Project	
Project	88.89%	Project	84.42%
No Project	88.89%	No Project	80.81%

Exam II

Two weeks following the Quiz, a common exam (Exam II) was given. There were 11 points related to GCA topics and 12 points related to the CPF topics on this exam. The results of this exam were used to measure the long-term effect of this teaching technique.

The percentage of correct answers for each project is shown in Table 2. There were different results depending on the project given. For Project B the students with the project scored higher than the students without the project on the CPF questions, but for Project A (GCA topics) the students without the project scored higher than the ones with the project. However, the chi-square test indicated that the effects of the self-managed learning projects were not statistically significant for Exam II.

Student Surveys—Quiz

Just prior to returning the Quiz, the students in both Groups A and B were required to complete a survey to determine their opinions on the usefulness of the projects in helping them (1) to understand their project topics, (2) in doing the homework related to their project topics, and (3) in preparing for the Quiz related to their project topics. In addition, six other questions were included on the survey related to the usefulness of both the textbook readings and examples in

(1) understanding the topics, (2) preparing the assigned homework, and (3) studying for the Quiz. The results of the survey and mean scores are shown in Table 3.

Table 2
Percentage of Correct Answers by Project Type
Exam II

GCA Project		CPF Project	
Project	78.79%	Project	73.81%
No Project	96.10%	No Project	66.67%

The researchers considered the topics covered in Projects A and B to be similar in level of complexity. Therefore, as expected, the students in both groups had similar mean scores pertaining to the usefulness of the projects in (1) understanding the project topics, (2) doing related homework, and (3) preparing for the Quiz (see Table 3). Also, as expected, the students in both groups had similar mean scores related to the usefulness of reading the textbook discussion and reviewing textbook examples.

The researchers had hoped that the students would find the self-managed learning projects to be more useful in (1) understanding the topics, (2) doing homework, or (3) preparing for the Quiz than reading the textbook or reviewing the textbook examples. Generally, the students in both groups found that their projects were as helpful or more beneficial than either reading the textbook discussion or reviewing the textbook examples. The only exception was that the Group B (CPF) students felt that reviewing textbook examples was more helpful in completing homework assignments than either reading the text or preparing the project (see Table 3). However, there were no significant differences.

The students in both groups indicated that reading the textbook was more helpful than reviewing textbook examples in understanding the appropriate topics. However, they found that reading the textbook and reviewing the textbook examples were equally beneficial in preparing for the Quiz [see Table 3].

Group A students indicated that the Project was more helpful in understanding the GCA topics than either doing the homework on the topics or preparing for the Quiz [see Table 3]. Group B students also found that the Project was most helpful in understanding the CPF topics. However, there were no significant differences.

Student Surveys—Exam II

Immediately before returning Exam II, the students in both Groups A and B were required to complete a survey to determine their opinions on the usefulness of the projects in (1) understanding the topics, (2) preparing the assigned homework, and (3) studying for Exam II. Also, the survey included questions related to the usefulness of both the textbook readings and textbook examples in (1) understanding the topics, (2) preparing the assigned homework, and (3) studying for Exam II. The results of the survey are shown in Table 4.

Table 3
Student Survey – Quiz
Mean Scores

	Group A (GCA)	Group B (CPF)
Reading the textbook gave me a thorough understanding of GCA (CPF) topics.	3.375	3.875
The **Examples** in the textbook greatly assisted me in obtaining an understanding of GCA (CPF) topics.	3.250	3.571
Preparing **Project** greatly assisted me in understanding GCA (CPF) topics.	4.125	4.286
Reading the textbook was very helpful in doing the homework on GCA (CPF) topics.	4.000	3.857
The **Examples** in the textbook were very helpful in doing the homework on GCA (CPF) topics.	3.750	4.000
My **Project** was very helpful in doing the homework on GCA (CPF) topics.	4.000	3.857
Reading the textbook greatly assisted me in preparing for the quiz on GCA (CPF) topics.	3.250	3.857
The **Examples** in the textbook greatly assisted me in preparing for the quiz on GCA (CPF) topics.	3.250	3.857
My **Project** greatly assisted me in preparing for the quiz on GCA (CPF) topics.	4.000	4.143

The students in Group A (GCA) felt that the project was more helpful than either reading the textbook or reviewing the textbook examples in (1) understanding the GCA topics, (2) preparing the homework, and (3) studying for Exam II [see Table 4]. However, Group B (CPF) students found the project most helpful in understanding the CPF topics. This group changed their opinions as to the usefulness of the project from the first survey after the Quiz. They no longer

felt that the project was more useful than reading the textbook or examples in preparing for a testing situation [see Table 4]. But, there were no significant differences.

Table 4
Student Survey – Exam II
Mean Scores

	Group A (GCA)	Group B (CPF)
Reading the textbook gave me a thorough understanding of GCA (CPF) topics.	4.125	3.429
The **Examples** in the textbook greatly assisted me in obtaining an understanding of GCA (CPF) topics.	3.750	3.714
Preparing **Project** greatly assisted me in understanding GCA (CPF) topics.	4.625	3.857
Reading the textbook was very helpful in doing the homework on GCA (CPF) topics.	4.000	4.000
The **Examples** in the textbook were very helpful in doing the homework on GCA (CPF) topics.	3.375	4.000
My **Project** was very helpful in doing the homework on GCA (CPF) topics.	4.250	3.857
Reading the textbook greatly assisted me in preparing for the Exam II on GCA (CPF) topics.	3.875	3.857
The **Examples** in the textbook greatly assisted me in preparing for the Exam II on GCA (CPF) topics.	4.000	3.857
My **Project** greatly assisted me in preparing for the Exam II on GCA (CPF) topics.	4.250	3.429

The opinions of Group A students as to the usefulness of the project increased between the two surveys [see Tables 3 and 4]. However, the opinions of Group B students as related to the usefulness of the project in understanding the topics and in preparing for a testing situation decreased between the two surveys. Again, there were no significant differences.

When comparing textbook reading to reviewing textbook examples, the students generally found both methods of learning to be equally helpful [see Table 4]. In fact, Group B indicated that reading the textbook and reviewing textbook examples were equally beneficial in doing homework assignments and in preparing for Exam II.

Group A indicated that the Project was more helpful in understanding the GCA topics than either doing the homework on the topics or preparing for Exam II [see Table 4]. However, no significant differences were found. Group B also found that the Project was equally helpful in understanding the CPF topics and in doing the assigned homework.

SUMMARY AND CONCLUSIONS

The results showed that the mean scores on the Quiz and Exam II were higher for the students with Project B (CPF topics) than the students without this project, but the chi-square test indicated that there were no significant differences. However, for the Project A (GCA topics) students, the mean scores on the Quiz and Exam II were equal to or lower than the students obtained without this project but again there were no significant differences.

This result is similar to the Hite and Parry (1994) study for their announced quiz and final exam. They found only major differences between the two treatment groups on the unannounced quiz given immediately after the experiment. The quiz results of our research do differ from Schadewald and Limberg (1990) who found that the students using self-generated explanations had a better recall on a test given six days after the instructional period ($p < .10$). The difference between our research and the Schadewald and Limberg research may be due to the different types of topics that the students were required to organize in the two studies. Our research and the Hite and Parry study required the students to be able to apply specific rules while the Schadewald and Limberg study requested the students to only understand the reasons why a tax law was enacted.

The students were surveyed both after the Quiz and Exam II to obtain their opinions on the usefulness of their projects, the textbook readings, and exams. On the survey following the quiz, both groups felt that the project was more helpful in understanding the topics and in preparing for the Quiz than either reading the text or studying the textbook examples. However, there were no significant differences. The students indicated on the survey after Exam II that they still ranked their projects to be more beneficial in understanding the topics than reading the text or reviewing the textbook examples, but there were no significant differences. The students in Group A felt that the GCA Project was more helpful in studying for Exam II and doing the homework than just reading the text or reviewing the examples, but Group B felt that their projects were least helpful in preparing for Exam II. However, there were no significant differences.

These self-managed learning projects, which required the students to be active participants in the learning process, were generally equally as effective in learning the governmental accounting topics (GCA and CPF) as either reading the textbook or reviewing the textbook examples. Thus, it appears that the self-managed learning project is a good alternative method of teaching moderately complex governmental accounting topics.

Further, our Project introduced the students to self-managed learning as advocated by the Quality Assurance Agency for Higher Education (2002). In addition, in the preparation of this Project, the students were active participants in the learning process as suggested by

Schulman (2005) and the AECC (1990). Also, the self-managed learning Project was beneficial because the Project did give the students experience in organizing information as recommended by the AECC (1990) and the AICPA Framework (1999). Further, the Project gave the students an opportunity to improve their written communication skills as recommended by the Pathways Commission (2012), the International Federation of Accountants in IES3 (2008), the Institute of Chartered Accountants in Australia and Certified Practicing Accountants of Australia in International Accreditation Guidelines for Accounting Degree Programs (2009), the Canadian Institute of Chartered Accountants in CA Skills and Competencies (2010), and PricewaterhouseCoopers in Educating for the Public Trust (2003).

ABSTRACT

This exploratory proposed that a luxury brand of nail polish (a product category that reflects hedonism) would have a higher proportion of brand names utilizing French words (which have been shown to have a hedonic connotation) compared to a non-luxury brand of nail polish. This proposition was supported.

KEYWORDS: Hedonic brands, Luxury, French Words, Content Analysis

INTRODUCTION

Developing appropriate and meaningful names for products is considered an essential element of effective brand management (Kohli and LaBahn, 1997; Ailawadi and Keller, 2004). Research has shown, for example, that consumers tend to draw inferences from brand names (Peterson and Ross, 1972). And, to the extent that the brand name reflects sound evidence, it serves to enhance the image of the brand which, consequently, leads to higher levels of brand equity. (Kohli, Harich, & Leuthesser, 2005)

It is not surprising, therefore, that market researchers have sought to understand the influence of brand name characteristics on consumer perceptions. At the most fundamental level, this research has resulted in the development of a set of general guidelines that include such things as: (1) distinguish the brand from competitive offerings, (2) facilitate learning of brand associations through suggestive names and/or the use of sound symbolism, (3) achieve compatibility with the desired image, and (4) be memorable and easy to pronounce. (Shimp 2010).

Of these, research on sound symbolism has been an enduring area of inquiry in the marketing literature. For example, Klink and Wu (2017) examined the influence of name characteristics on consumers' perceived ethicality of the brand. Among the findings, they showed that names with higher frequency sounds (i.e., commonly used words) convey greater ethicality than lower

frequency sounds (i.e., words that are more uncommon). Yorkston and Menon (2004) examined sound symbolism in an experimental design for hypothetical brands of ice cream and found that names with back vowel sounds (e.g., such as in 'boot') resulted in a greater preference for a hypothetical brand of ice cream than front vowel sounds (e.g., such as in 'beet'). Merskin (2007) content analyzed brand names from a sample of cosmetic companies and suggested that they tend to "optimize women's emotional connections with food, particularly desserts and rich beverages, through lipstick in two ways: (1) by symbolically consuming of the forbidden fruit and (2) by transforming oneself into the consumable." (587)

Sound symbolism has also been applied to studies of luxury brand names versus nonluxury names. In one of the earliest studies, Meyers-Levy (1989) hypothesized that luxury brands are more likely to use words that are relatively uncommon or distinct (what they term 'low frequency' words that have fewer implicit associations). By using terms that are uncommon (and thereby have fewer associations in memory), the luxury brand can facilitate greater *distinctiveness*, a desired characteristic of luxury brands.

In a related study, Pathak, Calvert, and Lim (2017) examined the linguistic structure of luxury versus non-luxury brand names and hypothesized that "the phonetic structures within luxury brand names are distinct from those of basic brand names and that these distinctions help to maintain the perception of exclusivity associated with luxury brands in consumers' minds." In essence, they argued that the objective of luxury brand names is to create a sense of exclusiveness in consumers' minds and thereby distinguish the luxury brand from non-luxury ones. They found luxury brand names differ from basic brands in their use of distinct phonetic features that can be formally identified: (1) luxury brands names have more syllables, (2) luxury brands are more likely to use back vowels, nasal, and affricates, and (3) luxury brands are more likely to use a higher number of stressed vowels.

The current study seeks to contribute to the body of knowledge on sound symbolism by examining an additional characteristic of sound symbolism; namely, the use of foreign brand names. Foundation for the study is provided by Salciuviene, Ghauri, Strider, and De Mattos (2010) who hypothesized that 'French' sounding brand names would be perceived as more *hedonic* relative to non-French sounding brand names. The results of the study supported the hypothesis that French-sounding words were associated with hedonism. This further validated the findings of prior research in this area (i.e., Thacker and Kohli, 1996; Leclerc, Schmitt, and Dubè-Rious, 1989). By implication, therefore, it would appear that the use French words for brand names of hedonic luxury goods might make sense.

First, we reviewed the relationship between hedonic goods and brand naming. As background, hedonic goods are characterized as ones "whose consumption is primarily characterized by an affective and sensory experience of aesthetic or sensual pleasure, fantasy, and fun" (61, Dahr and Wertenbroch, 2000; Hirschman and Holbrook, 1982). Conversely, utilitarian goods are "ones whose consumption is more cognitively driven, instrumental, and goal oriented and accomplishes a functional or practical task." (61, Dahr and Wertenbroch, 2000; Strahilcvitz and Myers, 1998).

Second, we reviewed the relationship between hedonic goods and luxury in order to identify evidence to support the relationship. Specifically, Kurnaz (2017) maintains that "Luxury items contain emotional value, and when consumers perceive a product to be exquisite, glamorous

and stunning, it creates a *hedonistic experience* for the owner and attributes the luxury product personal meanings (Turunen & Laaksonen, 2011, p. 469)." (109) Given: (1) the relationship between luxury and hedonism and (2) the hedonic connotation of French words, we conduct an exploratory analysis of two brands of cosmetic nail polish to determine the extent to which the luxury brand (i.e., Marc Jacobs) utilizes French brand names in greater proportion that the non-luxury brand of nail polish (i.e., Revlon). The cosmetic industry was selected as the unit of analysis based on the argument that cosmetic products have an inherent hedonic component (Hume and Mills, 2013). As such, it is a product category that appears highly suited to the analysis. While we would expect both brands to utilize French words, it is the luxury component that should help explain differences in proportions. That is, both brands are expected to use French words due to the inherent hedonism associated with the product category; however, given that one of the brands is from the luxury sector, we would further expect it to have a higher proportion of French-sounding brand names. The purpose of this study is simply to provide an exploratory analysis of this proposition.

METHOD

The first stage of the research process involved a content analysis of brand of nail polish. Two American brands of nail polish (one luxury and one non-luxury) were examined to identify the frequency of English versus French words in their sub-brand names. The data was then placed into a contingency table and a chi-square test for differences in proportions was conducted.

In the second stage, the French brand names were translated in English to obtain further insights into the sources of uniqueness. If the English translations reflect common words, it would suggest that the uniqueness of the brand name stems, not from the meaning of the word itself, but from the symbolism of the French language itself.

DATA PROFILES

For the comparison, we selected one luxury brand of nail polish and one non-luxury brand. To help avoid country-of-origin issues, we confined the study to nail polish from one country; namely, the United States. *Marc Jacobs* (n=35) is a well-recognized American brand nail polish and represents the luxury market. *Revlon* (n=59) is a well-recognized American brand of nail polish and represents the non-luxury market. The difference between the two brands, therefore, is the luxury component.

RESULTS

The results of the chi-square test for differences in proportions is presented in Table 1. Each data cell contains information on: the observed value (Obs Val), the expected value (Exp Val) and the individual X^2 values for each cell. The sum of the X^2 values is 8.3952 with 1 degree of freedom (p=.0038). Hence, the proposition that there would be differences in proportions was supported: the luxury brand has a higher proportion of French words.

Table 1: Contingency Analysis			
	Luxury Brand (Marc Jacobs)	Non-Luxury Brand (Revlon)	Marginal Row Totals
French Words	Obs Val = 9 Exp Val = 4.47 X^2 = 4.6	Obs Val = 3 Exp Val=7.52 X_2 = 2.73	12
English Words	Obs Val = 26 Exp Val = 30.53 X^2 = .67	Obs Val = 56 Exp Val = 51.47 X^2 = 0.04	82
Marginal Column Totals	35	59	94 (grand total)

In the second stage of the analysis, the French brand names were translated into English using one of the open-source translation programs available online. The results are presented in Table 2 and reveal that the words do not appear to have unique or distinctive meanings.

Table 2: French to English Translations	
Luxury Brand – Marc Jacobs	Non-Luxury Brand – Revlon
Oui! -> Yes	Romantique -> Romantic
Blaquer -> Fake French, similar to bloquer, to block/stop	Crème Brûlée -> Creme Brulee
Le charm -> The charm	Mauve -> Purple
Delphine -> Classic French name, associated with the noun dolphin	
Lux -> Luxury	
Lola -> A female French name	
Madame -> Mrs	
Louise -> A female French name, derived from the meaning "a famous warrior"	
Blanche ->White	

DISCUSSION

Developing an understanding of how branding elements can influence consumer perceptions has been an important component of the common body of knowledge in marketing. The results of the current study support the proposition that luxury brands will utilize French in greater proportion than non-luxury brands. Nonetheless, it was also argued that the inherent hedonic connotation of cosmetic products would suggest that even non-luxury cosmetics would utilize French words, just not in the same proportion and luxury brands. This proposition was also supported.

The analysis subsequently revealed that the French words, when translated to English, reflect relatively common terms. This was true for both the luxury and non-luxury brands. This suggests that it might be the symbolism of French words that help convey a higher image of luxury, rather than the actual meaning of the word itself.

Given the exploratory nature of this study, additional research may be warranted to examine the extent to which brand names reflect the evidence from the scientific literature. For example, it would be helpful to expand this line of research through an examination of other languages and cultures. Since language has been shown to convey a country-of-origin effect (Salciuviene, et al., 2010) and that the effect can differ across cultures (Strebinger & Rusetski, 2016), this might be a viable course of inquiry.

Additionally, this study was confined to only two brands within a single product category. While the results are encouraging, an examination using a larger sample would help establish the validity of these preliminary results. Furthermore, the research should be extended to other product categories to help establish the extent to which the results are generalizable. Finally, it is important to note that while the results are consistent with the evidence presented in the common body of knowledge, we do not know (and we did not test) whether brand managers utilized this knowledge when developing brand names or, instead, relied on other information. That was beyond the scope of this analysis. Further research may help determine the extent to which brand managers rely on scientific knowledge to guide their decision making.

In summary, the results are encouraging, but remain preliminary. Nonetheless, we are hopeful that the results will help stimulate further discussion and investigation of this phenomena.

The Use of Predictive Modeling in the Evaluation of Technical Acquisition Performance Using Survival Analysis

David E. Booth
Kent State University
dvdbooth8@gmail.com

Ceyhun Ozgur
Valparaiso University
ceyhun.ozgur@valpo.edu

Abstract: In the recent statistical literature, the difference between explanatory and predictive statistical models has been emphasized. One of the tenents of this dichotomy is that variable selection methods should only be applied to predictive models. Because it is well-known that explanatory models and predictive models are different. In this paper, we consider comparing the effectiveness of the acquisition strategies implemented by Google and Yahoo for the management of innovations. We argue that this is a predictive situation and thus apply lasso variable selection to a Cox regression model in order to compare the Google and Yahoo results. We show that the predictive approach yields different results than an explanatory approach and thus refutes the conventional wisdom that Google was always superior to Yahoo during the period under consideration.

Keywords: *Innovation Performance, Acquisitions, Innovation Knowledge, Hazards Model, Cox Proportional Hazards, Survival Analysis, Google, Yahoo, predictive model, explanatory model.*

Introduction

It is well known that management of innovation performance can be crucial to the success of a technology firm. Recently several authors have used survival analysis (also known as event history analysis) as a method to gauge the innovation performance of a firm. Most recently Datta and Roumani (2015) have attempted to do this by means of a proportional hazards (Cox) regression (Cox, 1972) model. We comment that such a time-to-event study is quite a reasonable approach to take but unfortunately the authors were unaware of the statistical difference between predictive and explanatory models as described in the seminal work by Shmueli (2010). This caused Datta and Roumani to confuse the techniques of explanatory modeling (which they used) in their analysis with the appropriate predictive modeling for the analysis of the proposed models. The present paper does the following, it

1) Argues that this is indeed a predictive situation as described by Shmueli (2010)
2) Treats the data analysis of the Cox Regression model, that Datta and Roumani treated by explanatory methods, by the appropriate predictive methodology (in this case adaptive lasso variable selection) and thus
3) Shows that the previous authors' conclusions were in error and
4) Draws the appropriate conclusions and shows that Datta and Roumani were in error in their overall conclusions

This paper thus provides a template for carrying out a statistical analysis of the performance effects of an innovation management program.

The Figure 1 shows the adverting revenues by companies, as you can see in the Figure 1. Google has most advertisement and highest percentage change.

Model Development

It is well known that Google and Yahoo have used acquisitions as a major part of a strategy to manage innovation performance (Datta and Roumani, 2015). In particular, both have tried to increase their pace of innovation by means of acquisitions. It would be ideal if a way was available to measure the success of each company's program. Datta and Roumani (2015) have attempted to do this by means of a proportional hazards (Cox) regression (Cox, 1972) model.

In order to do this, they posited a number of variables as being important to the company's success. They took the measure of innovation success to be the time to patent (TTP) and the time to launch (TTL) a product, where each was the first such event, which is the first such event of each type that happened after an acquisition measured in days, where a few observations were right censored. The data were found in publicly available data sources (Datta and Roumani, 2015). Because of the type of data a Cox regression seemed a reasonable way to start. They begin by setting up a set of hypotheses to be tested using the parameters of the Cox model and proceeded to test the hypotheses. This is a typical explanatory approach to modeling (Shmueli (2010)). However, for some time many statisticians have made the distinction between explanatory and predictive models. It is well known Shmueli (2010) that one type of model will not always replace the other. Further, the model building methods should often be different for the two types of models. We argue here that by the very method of a time-to-event study predictive modeling is the more appropriate approach. To see why this is so, let us consider the goal of the research. The main goal is to determine which organization made better use of the acquisition process. With their explanatory model, Datta and Roumani (2015) conclude that Google out performs Yahoo on both measures TTP and TTL. Let us now consider if an explanatory model is the most appropriate. Following Shmueli (2010), we wish to infer from the data which of Google or Yahoo has been most successful at using the adopted acquisition strategy as measured by TTL and TTP. In Section 1.5 of the work, Shmueli (2010) says that "Laws connecting sets of variables allow inferences or predictions to be made from known values of some of the variables to unknown values of other variables." Thus here we argue that what we really want to do is to infer whether Google or Yahoo produced the best application of its strategy in the two cases TTP and TTL. We argue that knowing which of the firms is making the best use of the adopted strategy is a forward-looking concept. This is an important distinction because the two types of models in a particular instance are often not the same and the methods used to construct the model are often different. We conclude that a predictive model is most appropriate and thus proceed to use variable selection model building techniques. In particular, shrinkage methods of regression are suitable for predictive but not explanatory models Shmueli (2010). We will show that the result of a predictive model analysis is not the same as an explanatory analysis and further we will show that the predictive model better answers the research question of which firm was most successful in applying each measure of a successful strategy. We further show that the distinction is important because the results of the two analyses are not the same.

Data and Methods

In this section, we discuss the methods that were used in the predictive analysis. The data set was that used by Datta and Roumani (2015) and is described there. We then arranged the data into four subsets for analysis labeled as:

GTTP YTTP
GTTL YTTL

*The Time to Patent (TTP) and The Time to Launch (TTL)

*Google(G), Yahoo(Y)

where the first letter represents the firm, Google or Yahoo, and the remainder of the name represents the dependent measure described. The size of these four sets is shown in Table 1. Cox propositional hazards regression (Cox, 1972) was chosen as the base for building the predictive model. The reason was that we wished to know which firm was more efficient in terms of the goals of patenting and bringing products to market. Outliers were identified by using the robust Cox regression estimator proposed by Faracomeni and Viviani (2011) that is based on trimming. The 5% outliers were removed and set aside for further analysis. The reason for this is that we want to be sure that we have the best measure possible of the average performance of the two firms. The final predictive model was obtained by using the adaptive lasso procedure for Cox regression (Zhang and Lu (2007), Lu et al., 2012, 2013) using a Bayesian Information Criterion (BIC). All final prediction equations were validated as described in Harrell (2001) using bootstrap cross validation with 150 bootstrap samples each, using Harrell's R packages. All computing was done in R. The Kaplan-Meier survival estimates were calculated with the final variable selected reduced Cox regression model as described in Lander (2013). The predictors were those of Tables 2-5. The chosen predictors had at least one non-zero Adaptive lasso coefficient. R programs and the data set are available from the authors.

Cox regression

Outliers can cause serious errors in Cox regression (Faracomeni and Viviani (2011)). Because we are building a predictive model we want the final model to represent the majority of data points without the possible deficiencies introduced by outliers by using the Faracomeni and Viviani (2011) procedure to ameliorate such outliers. We identified and removed the most serious outliers (5%). Because no other information was publically available about the observations removed nothing further was done with them. Table 1 shows the 5% outliers as defined in Faracomeni and Viviani's (2011) algorithm.

Table 1

5% Outliers

Data Set	N	Outliers
GTTP	63	10 13 36
GTTL	63	18 27 40
YTTL	55	13 23
YTTP	55	51 55

One of the major differences between explanatory and predictive modeling is the possible use of variable selection techniques to choose the independent predictor variables in the final selected predictive model. Because of its optimal predictive properties (Zhang and Lu (2007), Lu et al (2012), Lu et al (2013)) we chose adaptive lasso developed by Zhang and Lu (2007) to select the final predictive models for the data sets of Table 1 using a BIC criterion. All final prediction equations were selected by choosing the variables with non-zero adaptive lasso coefficients as shown in Tables 2-5. These prediction equations were successfully validated by bootstrap cross validation (Harrell (2001)) using 150 bootstrap samples each. Kaplan-Meier survival curves were calculated from the final prediction equations as described in Lander (2013). In the case of the Kaplan-Meier curves, the selected prediction equations contained all variables for which at least one Table showed a non-zero Adaptive lasso coefficient.

The analysis proceeds in the following manner. First, we know that outlying data points can cause errors in the conclusions drawn from a data analysis using Cox regression (Faracomeni and Viviani (2011), Lander (2013)). In order to deal with this potential problem, we begin the analysis by looking for outlying observations in our data set using the robust Cox regression method of Faracomeni and Viviani (2011) to identify the 5% outliers in the data. These results are indicated in Table 1. Again, because it is known that outliers are different from the majority of data observations, we removed the Table 1 outlying observations from the data sets and set them aside for separate analysis (Booth, 1984). Second, we then do variable selection on our four data sets after outlier removal in order to choose the optimal predictive model for each data set. Because of the many advantages of the adaptive lasso procedure (Zhang and Lu (2007), Lu et al (2012), Lu et al (2013)), we choose that method, using the R program of Zhang and Lu (2007), as reported by Boos (2014) using a BIC. These results are given in Tables 2-5. The final reduced prediction selected variables were those without 0 adaptive lasso coefficients using a BIC. Equations were validated using bootstrap cross validation with 150 bootstrap samples as described in Harrell (2001) using Harrell's R packages. The Kaplan-Meier survival curves were calculated for each of the selected models (Aalen et al 2008, Lander, 2013). The Google and Yahoo curves were then compared for the patent and product launch data sets to determine whether Google or Yahoo was

more successful in those particular cases over the years studied. The lower of the two curves shows the firm that is the faster of the two in getting patents approved or launching products(Lee, 1992). All programs and data sets are available from the author (DEB).

Discussion of Products for both Yahoo and Google

The results of the analysis are shown in Tables 1-5 and Figures 2 and 3. It is interesting to note the similarities of the Tables. In the patent case (Tables 2 and 5) the major predictor selected was Product_or_Process for both Yahoo and Google. While country was selected for only Yahoo both variables were included in the rest of the analysis. In the product launch case (Tables 3 and 4) new_incremental was selected for both but size of knowledge base was also included in the further analysis even though that selection was specific to Google. It is reassuring to note that the major predictor variables selected in the patent and launch cases were essentially the same for both firms indicating the major drivers were the same in both cases.

We now consider the Kaplan-Meier (Lachin, 2011), (Lee, 1992) curves for the above models. For the Kaplan-Meier curves, in the Time to Patent case (Figure 2) Yahoo is the lower curve while in the Time to Launch case (Figure 3) Google is the lower curve. In both cases there is very little overlap between the 95% confidence bands. In the Kaplan-Meier curves the lower the curve the faster the event happens (Lee, 1992). Hence Yahoo was faster patenting but Google was faster launching products. Because Google was undoubtedly the market leader during this period (Datta and Roumani (2015)) this would indicate that the speed of bringing products to market was a key factor in the competitive leadership at this point in time given that both firms had similar strategies subject to the limitations of the analysis to be described in a moment. This results in variance with the Datta and Roumani (2015) result based on an explanatory model analysis. We suggest based on the previous discussion that the predictive model is to be preferred and hence that the result reported here is to be preferred.

Limitations

There are, of course, limitations to this analysis. These are mostly caused because some information is proprietary. The biggest two such pieces of information that are missing are the amount spent on research and development for each of these products and the amounts spent for marketing the products. Either or both of these sources of funds could have shortened the time for patenting and launching the products. Thus varying amounts spent could have an effect that should have been included in the Kaplan-Meier curves. However, the amounts spent are known only to the two firms.

Conclusion

Since we use adaptive lasso (a variable selection method) the model we built must be predictive. We further argue that the appropriate model in our case is predictive not explanatory before the

model building steps are introduced. We avoid the fact that the use of Cox regression in the original paper (Datta and Roumani (2015)) is incorrect. They have treated the Cox regression coefficients as if they are estimated by least squares which are not the case for Cox regression. Based on our analysis we conclude that Google was more effective at bringing products to market and that Yahoo was more effective at getting patents during the periods studied and that predictive models are more appropriate for this application than explanatory models.

ABSTRACT

We study online crowdfunding as a tool to increase funding for emergency relief campaigns. Crowdfunding campaigns can use two tools to increase the transparency provided to potential donors: certification and online updates. Certification is a form of conventional transparency that ensures the campaign is benefiting a charitable purpose. Alternatively, updates are additional status posts and are a form of operational transparency when they communicate the work of the campaign. Using data from a large crowdfunding website, we show that work-related updates (operational transparency) have a stronger effect on increasing donations than certification (conventional transparency).

ABSTRACT

To what extent does a political candidate's social media presence influence people's views and their real-world political activities? We conducted a survey using Mechanical Turk asking questions about social networking use and political involvement with regard to the 2016 presidential election. We asked factual questions about politics to gauge political knowledge. We find low-information voters are more easily influenced by friends' posts and are more likely to be influenced by candidates' social media to change real-world political activities; in contrast, high-information voters are less easily influenced by friends' posts and less likely to be influenced by what candidates post.

KEYWORDS: Social media, political knowledge, participation

INTRODUCTION

Tens of millions of people are using social networking sites (SNS), and social media use has exploded in recent years. Businesses, celebrities, and politicians are trying to use this to their advantage. In particular, politicians now have a new method through which they can reach out to large numbers of people in a relatively inexpensive way (Gueorguieva 2008), with presidential candidates relying on Facebook and Twitter to communicate directly with voters (Kreiss 2016). However, the effectiveness of using social media in this way for political gain is still a matter of debate.

A growing literature discusses the connections between SNS and political participation. Studies have examined how candidates for office use their public pages (Robertson, Vatrapu, and Medina 2010; Haynes and Pitts 2009; Williams and Gulati 2013); how those pages create space for political discourse (Robertson, Vatrapu, and Medina 2009); if SNS are altering basic democratic values (Swigger 2013); and whether SNS encourage people to become politically active (Conroy, Feezell, and Guerrero 2012; Baumgartner and Morris 2010; Bode 2012; Vitak et al. 2011; Vesnic-Alujevic 2012; Towner 2013; Zhang, Seltzer, and Bichard 2013; Dimitrova and Bystrom 2013; Bode et al. 2014). In one notable recent study, a 61 million person experiment of Facebook users was conducted to see if political messages would

mobilize people to be politically engaged. They concluded that the messages affected political behavior both online and offline (Bond et al. 2012).

Others, however, have argued that the high hopes surrounding the possibilities of online political discussions have not yet been fulfilled (Larsson 2013). There is, so far, no consensus in the existing literature on whether or how offline and online political activities influence each other, with some studies seeing a direct connection and others separating the two. Clearly much work on understanding the impact of the Internet on politics remains to be done (Farrell 2012).

We propose here to expand on this literature by examining the extent to which a political candidate's social media presence influences citizens' views on candidates for high public office and their real-world political activities. In particular, we are interested in understanding how political knowledge (or lack thereof) mediates the relationship between politicians' social media use and the ways average citizens behave as a result. We recruited 717 subjects for a survey via Amazon.com's Mechanical Turk platform. The survey asked questions about their demographic and political characteristics, social media use, the extent to which they are influenced by politicians' presence on social media, as well as questions about their level of political knowledge. The results suggest an important role for political knowledge in mediating the relationship between politicians and citizens on social media platforms. This has important implications for our democracy: to the extent that people's lack of knowledge informs their political actions online, the discourse on social networking sites may be significantly poorer as a result.

LITERATURE REVIEW

The literature on social media use by citizens is divided on the question of whether users of social networking sites are more or less likely to be politically engaged as a result of their social media use. Baumgartner and Morris (2010), Kushin and Yamamoto (2010), and Larsson (2013), for instance, found that users of SNS were no more likely to engage in offline political participation than those without social networking accounts. Harlow and Guo (2014) also suggest that digital communication tools may lead users to engage in "clicktivism" rather than real-world activism, while Theocharis and Lowe (2016) find that Facebook use actually negatively correlates with political and civic participation. A study by Richey and Zhu (2015) also found that Internet usage does not improve political efficacy, political interest, or political knowledge for late adopters of this technology. Qiu et al (2015) find that network effects help content to go viral.

On the other hand, studies by Bode (2012), Towner (2013), Towner (2017), Rice et al. (2013), and Zhang et al. (2013) did find a positive relationship between online social media political involvement and real-world political participation. Pasek et al. (2009) argue that different types of social networking sites will affect offline participation in different ways, and Chan (2016) similarly notes that the size of a person's Facebook network affects their political participation on that site. The massive experiment conducted by Bond et al. (2012) also found that political messages posted on people's Facebook news feeds did cause those targeted to become more active in politics, to be more likely to vote, and more likely to influence their friends to participate in politics as well. Similarly, a meta-analysis by Boulianne (2015) found that there is generally a positive relationship between social media use and real-world participation, both in the U.S. and across the world. Bimber and Copeland (2013) qualify some of this by suggesting that the relationship between digital media use and political participation may vary over time.

A subset of this literature on the relationship between social media and political participation examines the question of how political knowledge affects the relationship between social media usage by political actors and citizens' involvement in political activities. Although knowledge of political affairs is a key component of civic understanding and political participation (Galston 2001) most Americans seem to have a somewhat limited understanding of the details of politics and policy (Delli Carpini and Keeter 1996). Scholars have long understood that political information is not evenly distributed among the public, with important implications for understanding vote choice (Converse 1962, 2000). Some studies demonstrate a link between gaining knowledge about the issues and the public's judgment of those issues (Gilens 2001), with misleading information having a detrimental effect on that judgment (Jerit and Barabas 2006). Many studies have shown that partisanship acts as an important informational cue, especially for low-information voters (Bartels 2002; Bolsen, Druckman, and Cook 2014; Jerit and Barabas 2012; Schaffner and Streb 2002). Increased levels of partisan polarization in recent decades have also significantly affected the information environment by making party endorsements more important and decreasing the relevance of substantive information (Druckman, Peterson, and Slothuus 2013). Bullock (2011), however, argues that the impact of partisan cues has been overstated, at least for citizens who already possess good information about policy.

Kenski and Stroud (2006) suggest that the Internet does contribute positively to political knowledge, though the overall effect in their findings is small. Similarly, a study by Cacciatore et al. (2014) argues that Internet use can narrow knowledge gaps in the public. Dimitrova et al. (2014), however, suggest that the effects of online media consumption may assist only weakly in political learning with some possible effects on greater political participation. In a similar vein, Baumgartner and Morris (2010) show that, while social networking may be a potential tool for people to increase their political knowledge, the news gathered this way does not tend to enhance democratic discourse. As they note, "there is little evidence to suggest individuals who get their news about politics on SN Web sites are well informed" (Baumgartner and Morris 2010, 34).

On the other hand, Groshek and Dimitrova (2011, 368) argue that "more frequent exposure to Internet news and more attention to campaign information online was a significant predictor of political knowledge." Tran (2013) also suggests that online news use does lead to gains in political knowledge. Kaufhold et al. (2010) compared the effects of professional and citizen journalism, finding that consumers of professional journalism were slightly better informed, but that consumption of any form of news tended to produce more political involvement. Bode (2016) presents a more nuanced view that citizens may be *able* to learn more from social media, but do not always do so in practice. Similarly, Towner (2017) found that, while offline sources do not affect young adults' levels of political knowledge, some types of online information (specifically those from online newspapers and television campaign websites) are linked to improved political knowledge levels. This literature does not, however, fully examine whether political knowledge may act as a mediating influence between what political actors post on social media and how citizens' involvement in political activities is affected as a result.

HYPOTHESES

Researchers have found a positive relationship between political involvement on social media and real world participation (Bode 2012; Towner 2013; Towner 2017; Rice, Moffett, and Madupalli 2013; Zhang, Seltzer, and Bichard 2013). News gathered through SNS does not necessarily keep people well informed (Baumgartner and Morris 2010), and yet those who

consume any form of news tend to have more political involvement (Kaufhold, Valenzuela, and Zúñiga 2010). However, those with lower levels of political knowledge may be more easily influenced by their exposure to the media environment (Galston 2001; Lupia 2016).

Therefore, we hypothesize:

H1. Low-information voters will be more easily influenced by friends' posts and more likely to be influenced by candidates' social media presence to change their real-world political activities (such as voting or donating to the campaign).

In the current era of growing partisan polarization, party endorsements have become ever more important and the relevance of unbiased information has decreased (Druckman, Peterson, and Slothuus 2013). Bullock (2011), however, argues that the impact of partisan cues has been overstated for citizens who already possess good information about policy. In contrast, those with less information in any political party will be at a disadvantage.

Therefore, we hypothesize:

H2. *Low-information voters will be more easily influenced by friends' posts and candidates' social media presence regardless of their political party.*

MECHANICAL TURK AS A RECRUITMENT TOOL

Mechanical Turk is a relatively new platform that acts as an online labor market. Participants who wish to serve as subjects or are willing to carry out various tasks are paid relatively small sums of money (often as little as 10 cents) for their time. Requesters, often conducting various types of research, are thereby able to recruit large numbers of subjects at minimal cost. The total number of participants on Mechanical Turk is estimated at over 500,000. The effectiveness of this method of subject recruitment has been demonstrated in recent studies that find MTurk samples to be generally reliable and comparable to more expensive methods (Berinsky, Huber, and Lenz 2012; Buhrmester, Kwang, and Gosling 2011; Chandler, Mueller, and Paolacci 2014; Horton, Rand, and Zeckhauser 2011; Mason and Suri 2012; Shapiro, Chandler, and Mueller 2013; Berinsky, Margolis, and Sances 2014; Clifford, Jewell, and Waggoner 2015; Huff and Tingley 2015; Ipeirotis 2010; Levay, Freese, and Druckman 2016). Studies using MTurk have been published in fields as diverse as political science, psychology, computer science, and economics (Berinsky, Huber, and Lenz 2012; Horton, Rand, and Zeckhauser 2011; Amir, Rand, and Gal 2012; Grose, Malhotra, and Parks Van Houweling 2015). This new platform opens up the possibility of recruiting a larger number of subjects with relative ease and at low cost.

METHODOLOGY

We recruited 717 participants via Mechanical Turk (332 female, 383 male, and 2 who identified as other). We limited the survey only to those in the United States, and it was open from November 5, 2016 – November 7, 2016 and therefore closed before Election Day. All participants received 40 cents to answer our survey. Before beginning, participants had to affirm that they had either a Facebook account or Twitter account and were eligible to vote in the U.S. election. They were then asked to select whether they had a Facebook account,

Twitter account, or both. 232 respondents (32.36%) had only a Facebook account, 25 (3.49%) had only a Twitter account, and 460 (64.16%) had both a Facebook and Twitter account.

Using a Likert-scale from 1-5 where 1 is *Strongly Disagree* and 5 is *Strongly Agree*, we asked participants a series of questions pertaining to their social networking and political activity, broken down into four different categories: their social networking usage (Facebook or Twitter), political activity, their political activity on social networking sites, and the influence candidates and their friends on SNS had on modifying their political beliefs.

Statements on SNS Activity (*SNS_Active*):

I check my social networking site often
I post on my social networking site
I read people's posts often
I reply to people's posts often

Statements on Political Activity (*POL_ACTIVE*):

I volunteer in support of political causes
I attend political events
I have worked for candidates for office
I have donated to candidates for office

Statements on Political Activity on SNS (*POL_ACTIVE_SNS*):

I have joined political discussions through a social networking site
My status updates are often about political events
My status updates are often about political candidates

Statements on Politically Influenced on SNS (*POL_INFLUENCED_SNS*):

A political candidate's active presence on a social networking site affects my decision on how to vote

A political candidate's active presence on a social networking site affects my willingness to donate to his/her campaign

I often change my mind based on my friends' political opinions via social networking sites

I often change my mind based on my friends' opinions on political candidates via social networking sites

These items loaded into their respective factors, and Cronbach's Alpha is .85 for SNS_ACTIVE, .88 for POL_ACTIVE, .86 for POL_ACTIVE_SNS, and .83 for POL_INFLUENCED_SNS. Four statements that did not load into these factors were removed.

Furthermore, we asked participants five factual questions about political issues to gauge their level of political knowledge. These questions are, word for word, the same ones used as part of the pre-election survey conducted by the American National Election Study (http://www.electionstudies.org/studypages/anes_timeseries_2012/anes_timeseries_2012_qnaire_pre.pdf) as part of its massive panel study during every presidential election year. These questions are therefore a reliable and proven method for measuring political knowledge. See questions below:

Do you happen to know how many times an individual can be elected President of the United States under current laws?

1. Once
2. Twice
3. Three Times
4. Four Times

Is the U.S. federal budget deficit – the amount by which the government's spending exceeds the amount of money it collects – now bigger, about the same, or smaller than it was during most of the 1990s?

1. Bigger
2. About the Same
3. Smaller

For how many years is a United States Senator elected – that is, how many years are there in one full term of office for a U.S. Senator?

1. 2 years
2. 4 years
3. 6 years
4. 8 years

What is Medicare?

1. A program run by the U.S. federal government to pay for old people's health care
2. A program run by state governments to provide health care to poor people
3. A private health insurance plan sold to individuals in all 50 states
4. A private, non-profit organization that runs free health clinics

On which of the following does the U.S. federal government currently spend the least?

1. Foreign aid
2. Medicare
3. National defense
4. Social Security

We added the results of the five political knowledge questions together for each participant to get their *political knowledge score* in order to determine the relationship between political knowledge score and participants' likelihood to be influenced by SNS.

RESULTS

The mean, maximum, minimum, and standard deviation of the respondents' political knowledge scores as well as their SNS activity, Political Activity, Political Activity on SNS, and their level of Influence through SNS can be seen in Table 1.

Table 1. Participants' Average Political Knowledge Score and Political and SNS Activity (N=717)

Variables	Mean	Std Dev	Minimum	Maximum
Political Knowledge Score	3.62	1.05	0	5
SNS_ACTIVE	3.54	0.90	1	5
POL_ACTIVE	2.00	1.02	1	5
POL_ACTIVE_SNS	2.33	1.09	1	5
POL_INFLUENCED_SNS	2.03	0.86	1	5

Table 2 shows the breakdown of participants' demographics and political knowledge scores. Spearman's rank correlations were computed and there were significant and positive relationships between education and score (ρ=0.20187, p<.0001) and age and score (ρ=0.21256, p<.0001). The more educated and older participants were, the better their political knowledge scores. The results of t-tests show that there were no differences between males and females with regard to their political knowledge score,t(713)=-.89, p=0.37, or whites and non-whites, t(715)=0.07, p=0.95. In addition, using an ANOVA we found no differences in political knowledge score between Republicans, Democrats, and Independents, F(2, 693)=0.48, p=0.62.

Table 2. Participants' Demographic Information and Political Knowledge Scores (N=717)

Demographics	N	Score	Std Dev
Ethnicity			
White	555	3.62	1.04
African American	49	3.27	1.04
Asian American	55	3.91	1.02
Hispanic	38	3.47	1.25
Native American	4	3.75	0.5
Other	13	4.08	0.64
Prefer not to answer	3	4.33	1.15
Education			
Did not complete high school	1	5	.
High school Graduate / GED	71	3.32	1.09
Some college / Associate degree	247	3.44	1.08
College graduate	303	3.70	1.00
Postgraduate degree	95	4.05	0.93
Gender			

Female	332	3.59	0.94
Male	383	3.66	1.14
Other	2	2.5	0.71
Age			
18-25	106	3.24	1.12
26-30	157	3.46	1.13
31-40	214	3.63	1.01
41-50	107	3.84	0.97
51-60	89	3.87	0.92
61-70	38	4.11	0.83
70+	6	4.17	0.75
Political Orientation			
Democrat	336	3.61	1.04
Independent	217	3.67	1.05
Republican	143	3.57	1.09
Other	21	3.81	0.93

Participants generally checked their social networking sites (Facebook and/or Twitter) often. See Table 3 for a breakdown of how often participants checked their social networking sites. Over 80% checked their SNS at least once a day (column 2). While Table 1 shows that participants were not very politically active, Table 3 reveals that over 70% of the participants discussed political events (column 3) and the presidential election (column 4) at least a few times a week. Spearman's rank correlations show a negative relationship between the frequency of checking SNS with their political knowledge score (ρ=-0.09, p=0.01). The lower the score, the more they checked SNS. However, there were no significant correlations between the number of times they discussed political events (ρ=0.03, p=0.42) or the 2016 election (ρ=0.06, p=0.09) with their political knowledge score.

Table 3. Frequency of SNS Usage and Political Discourse

	Check SNS	**Discuss Political Events**	**Discuss 2016 Election**
At least a few times a day	410 (57.18%)	114 (15.90%)	138 (19.25%)
About once a day	182 (25.38%)	192 (26.78%)	190 (26.5%)
At least a few times a week	80 (11.16%)	220 (30.68%)	206 (28.73%)
Once a week	25 (3.49%)	98 (13.67%)	113 (15.76%)
Less than once a week	20 (2.79%)	93 (12.97%)	70 (9.76%)

On a 5-point scale ranging from not at all likely to very likely, 542 (76%) of the respondents stated that they were very likely to vote, and another 78 (11%) said they were likely to vote. The mean for likelihood to vote was 4.5.

Table 4 shows a correlation matrix depicting significant and negative relationships between political knowledge score and SNS_ACTIVE, POL_ACTIVE, POL_ACTIVE_SNS, and POL_INFLUENCED_SNS. The lower the score, the more likely participants were to be active on SNS, politically active, politically active on SNS, and influenced by a candidates' presence on SNS as well as by their friends' political opinions on SNS. While it is statistically significant, the correlation coefficients are relatively low in terms of practical significance. The largest coefficient is with the negative relationship between participants' political knowledge score and level of political influence on SNS. There is a negative relationship showing the more they were influenced on SNS the lower their political knowledge score, which supports H1. While the direction as we hypothesized was negative and significant, it was not too strong (ρ=-.26). However, even small impacts can have the potential to help determine an election.

Table 4. Pearson Correlation Matrix (N=717)

	Political Knowledge Score	**SNS ACTIVE**	**POL ACTIVE**	**POL ACTIVE SNS**	**POL INFLUENCED SNS**
Political Knowledge Score	1	-0.13**	-0.12**	-0.15**	**-0.26*** **
SNS ACTIVE		1	0.18**	0.45***	0.24***
POL ACTIVE			1	0.54***	0.43***
POL ACTIVE SNS				1	0.46***
POL INFLUENCED SNS					1

*p<.05; ** p<.01; *** p<.001

Tables 5-7 show correlation matrices broken down by political party. For all party affiliations (Democrat, Republican, and Independent) there was a significant and negative relationship between political knowledge score and politically influenced on SNS. Therefore, H2 was supported. The lower the political knowledge score, the more likely participants were to be influenced by their friends' statuses as well as by candidates' presence on SNS, regardless of whether they were Republicans, Democrats, or independents. Using Fisher's r to z transformation, we were able to calculate the z values in order to assess whether there were any significant differences between political parties and their level of influence on SNS (POL_INFLUENCED_SNS). The differences between the correlations were not significant (Influence between Democrats and Republicans: Z=0.87, p=0.38; Independents and Republicans: Z=1.1, p=0.27; Democrats and Independents: Z=-0.36, p=0.72).

Table 5. Pearson Correlation Matrix For Democrats (N=336)

	Political Knowledge Score	**SNS Active**	**POL ACTIVE**	**POL ACTIVE SNS**	**POL INFLUENCED SNS**

Political Knowledge Score	1	-0.12*	-0.07	-0.14*	**-0.25*** **
SNS ACTIVE		1	0.21***	0.47***	0.22***

DISCUSSION

The results we have reported above suggest several tentative conclusions about the mediating role of political knowledge on the relationship between political candidates' use of social media and citizen involvement in political affairs. The hypotheses we laid out at the beginning seem to be borne out: citizens with low levels of political knowledge are more likely to be influenced by the posts of their friends as well as a candidates' presence on social networking sites to change their real-world political behaviors, in particular to vote for them or donate to them. Those with greater levels of political knowledge, on the other hand, are less likely to be influenced by candidates' SN presence to carry out those activities. These findings seem to hold true across lines of political party affiliation. All parties showed a significant and negative relationship between their political knowledge score and level of influence via SNS. Similar to the findings in studies by Baumgartner and Morris (2010), Bode (2016), Dimitrova et al. (2014), and Richey and Zhu (2015), who have examined the relationship between Internet usage and political knowledge, this suggests reasons for skepticism about the possibility of social networking usage being a tool for enhancing political knowledge.

Interestingly, though the coefficients were not too strong, we did see patterns emerging that those with higher levels of political knowledge reported being less active on SNS, politically active, and politically active on SNS than those with low levels of political knowledge. In contrast, those with low political knowledge scores were more likely to be active. To the extent that social media is flooded with posts by people with low levels of information about politics and policy (Delli Carpini and Keeter 1996), we should be concerned that democratic citizenship may be damaged through the sharing of incorrect information, or at least information not subject to critical scrutiny (Farrell 2012). Online deliberation has been shown to over-represent certain demographic groups (Baek, Wojcieszak, and Carpini 2012), but it may also be the case that political conversations via social media are also more likely to be sidetracked through disinformation and lack of policy understanding. Partisanship did not seem to be particularly relevant, with most of the results (people's political activities on SNS, and being politically influenced by SNS) suggesting that Democrats, Republicans, and Independents all behave in similar ways.

The comments left by some survey respondents indicated that their misunderstandings of certain policy issues run quite deep. One of the political knowledge questions was about federal government spending:

> On which of the following does the U.S. federal government currently spend the least?
> 1. Foreign aid
> 2. Medicare
> 3. National defense
> 4. Social Security

The correct answer is foreign aid. At least two survey responders commented with specific reference to the fourth choice, Social Security. One remarked, "Social Security is NOT funded by the government." Another said, "I may be mistaken, but I think that Social Security is funded by those who have paid into it in the past. I keep hearing that it will run out of money in the near future." Both of these are misunderstandings of how the program operates; the first is a clear factual error, but even the second confuses the status of the Social Security trust fund with current Social Security payments in the overall federal budget (see https://www.ssa.gov/pubs/EN-05-10024.pdf). Contrary to many onlookers' hopes (Bimber 2003), people with incorrect information may be driving online debates about politics, to our detriment as a democratic polity.

One potential limitation of this study is that we have only examined results from one election cycle. As Bimber and Copeland (2013) suggest, the relationship between Internet usage and political activity may vary as patterns of Internet usage change, Future research in this vein should continue to examine these questions in other elections, especially to see if these results hold true in midterm elections as well as in presidential election years. Additionally, future research should expand the range of social networking platforms examined, including others such as Snapchat or Instagram.

CONCLUSION

This study has examined the question of how political knowledge mediates the relationship between political candidates' use of social media and how citizens respond to them. We find that there is a significant and negative relationship between political knowledge and SNS activity, political activity, political activity on social networking sites, as well as being politically influenced via those sites. Those with less political knowledge are more likely to be

influenced by their friends' statuses as well as by candidates' presence on SNS. Our findings should be seen as a step toward deeper examinations of this topic. Future research should examine the extent to which this relationship persists across different election cycles, especially to compare midterm and presidential-election years, as well as examining the strength of this relationship across time. We also suggest that scholars should continue to explore whether lack of political knowledge is an insuperable obstacle to democratic citizenship online, or if learning can occur to improve deliberation.

ABSTRACT

The main contribution of the paper is in proposing a model that relates the buying firm's level of risk associated with the purchase of critical inputs to the disclosure, by the supplier, of input information characteristics and means of production. It suggests that as the level of risk and seclusion of information increases, buying firms will tend to engage in more complex contracts with their suppliers to safeguard their position. Implications for further research are discussed.

KEYWORDS: Asymmetry, information, credence, uncertainty, competitiveness

INTRODUCTION

One of the main problems faced by managers in the food industry is how to guarantee the delivery of wholesome and safe food to markets. Since the mid-nineties both the US and the European Union engaged in intensive legislative activity to increase food safety, through pathogen and contaminants reduction (Hennessy, Roosen, & Jensen, 2003). Under this changing environment, where firms face increasing pressure from governments, and are increasingly being liable for failing to meet safety standards, it is important to understand how management strategies are developing. Furthermore, consumers are now demanding a larger variety of products, there is increasing vertical integration and horizontal consolidation of firms at all levels of the supply chain and retailers have increasing power and are demanding more value from other players in the supply chain (Kinsey, 2003). Managers of large food processing corporations such as Nestle, General Mills, or Heinz, have to be increasingly concerned with the quality and safety of their inputs and at, the same time, are being forced to deliver more attributes for less money by retailers.

A central problem with food safety is asymmetric information on the quality of inputs, which leads to uncertainty, increasing risks and market failures with considerable economic and political consequences (Hennessy et al., 2003). The development of suitable policies to reduce food safety hazards has been extensively treated by economists in recent years. In the US there is increasing consensus that performance standards are more effective than command and control ones in achieving food safety. Even though firms have more flexibility under performance standards, managers will face increasing pressure as now they have to make strategic and

tactical decisions leading to compliance with food safety goals. The objective of this paper is to shed light into decision-making on a complex environment where there is asymmetric information on the characteristics of inputs, opportunities to seclude crucial information on input characteristics and risks of being held accountable for problems originated on inputs. It analyzes the vertical relationships between firms in sequential tiers of a supply chain, reasoning about different options available using the resource-based view (RBV), transaction costs economics (TCE), and to some extent, institutional theory frameworks.

BACKGROUND

In the field of strategic management, asymmetric information has been treated in the context of vertical integration, diversification and consolidation strategies (Prahalad and Bettis, 1986; Chatterjee and Wernelfelt, 1991; Reuer and Koza, 2000; Hennart and Reddy, 2000). The transaction cost theory and resource-based view have both been used to develop frameworks on which to evaluate and propose strategies leading to merger between firms. There has not been much focus of the resource-based view on the food industry.

Before making a purchase, buyers need information about the price and quality of the good or service that they are considering to purchase. Obtaining this information is particularly difficult in the case of a most credence goods or services because of their intangible nature. What makes particularly difficult for the consumer is the standard credence good problem, i.e., the asymmetrical nature of information they possess. The seller often knows more about the quality of the good or service than the uninformed consumer him/herself (Bester & Dahm, 2018). The veracity of a credence good depends on trusting the word of the seller, and service goods are simultaneously consumed while being produced (Mills, 1986; Nayyar, 1990). As shown in Table 1 below, the most recent research on information asymmetry has discussed the prevalence of misleading and deceptive credence claims in market place, specifically dividing them into broad three broad categories related to provenance of the good/service, where it was manufactured or produced, and its quality (Hobill & Sanderson, 2017).

Table 1: Deleterious Claims that Information Asymmetry May Conceal

Categories	Types of claims
Sources/derivation of foods or products	Claiming that foods are sourced from, or made in, a particular location when they are not, e.g., claiming that a food or product is manufactured or produced in the America, when it is not.
Manufacture and production of foods	Claiming that foods are produced or manufactured in a particular way when they are not, e.g., claiming that eggs are from ‘free-range’ or ‘free to roam’ hens, when it is not; or that mean was prepared ‘kosher’ when it was not.
Qualities and characteristics of foods	Claiming that foods have a particular standard, quality or value when they do not, e.g., claiming that a beverage contains ‘real’ fruit or is ‘healthy’ when it does not; or that bread is ‘fresh’ when it is stale.

It is also more difficult for the buyer to obtain information on the costs involved in producing the good or service to be able to estimate the value added to the final product or service they are

considering to purchase (Stigler, 1961). Sellers, on the other hand, possess greater information about their product or service than buyers, which is the basis of information asymmetry (Nayyar, 1990). In situations where buyers lack such key information, the resultant buyer-seller information asymmetry provides buyers with the opportunity to engage in behaviors that may be detrimental to the buyer. According to agency and moral hazard theories, these situations may provide agents (managers or sellers) with opportunities to engage in self-aggrandizing behavior vis-à-vis their clients (or owners or customers) with relative guile and impunity (Richardson, 2000; Williamson). This is done by the "incomplete or distorted disclosure of information, especially to calculated efforts to mislead, distort, disguise, obfuscate, or otherwise confuse" (Williamson, 1985: 47). Furthermore, when sellers do not bear full responsibility for the costs or risks associated with their products, not only are they inclined to raise prices, but they are also likely to exercise less effort toward reducing the costs (Holmstrom, 1979; Pauly, 1974). In fact, lately some research has revealed that moral hazard is not limited to its primary manifestations, but is often ramped up to what has become known as second-degree moral hazard (Balafoutas, Kerschbamer, & Sutter, 2017). This has been reported in the market for taxi rides, where moral hazard was empirically observed to exhibit a significant positive effect on the likelihood of overcharging when passengers had explicitly stated that their expenses would be reimbursed their employers (Balafoutas, et al. 2017).

Different institutional arrangements are suggested when the levels of risk and information seclusion on relevant characteristics of inputs. When the risk of inputs and information seclusion is low, the market is a reliable and probably the most efficient institution. However, if risks and seclusion levels are high, buyer will better engage in hard contract to safeguard their position. From this framework three propositions are derived and commented below. The paper is divided into five parts. The introduction is followed by a section two, which reviews the most recent literature specifically related to the resource-based view and transaction cost economics theory. Section three presents a series of proposition that summarize the options available to firms. This is followed by section four that discusses of the implications of the propositions. The paper ends with a concluding section that offers suggestions for future research.

LITERATURE REVIEW

This second part reviews relevant literature in asymmetric information, the resource based view (Barney, 2001; Priem & Butler, 2001; Penronse, 1959; Verbeke & Kano, 2012); transaction cost theory (Coase, 1937; Madhok, 2002; Tong & Crosno, 2016; Williamson, 1989); and institutional theory (DiMaggio & Powell, 1983; Haveman, 1993; Scott & Meyer, 1983; and Tolbert & Zucker, 1996). The latter, especially through mimetic isomorphism – the achievement of conformity through imitation (DiMaggio and Powell. 1983: 151-152) – is one of the processes through which organizations change over time in due to pressure to conform with other organizations in their environments. Researchers in institutional theory assert that mimetic isomorphism can result from efficient responses to uncertainty (DiMaggio and Powell, 983).

Asymmetric information on quality of inputs

In several industries characteristics of the inputs are directly associated to those of the products from them derived. Information on the attributes of inputs is then critical to managers, as the efficiency of processing or manufacturing and the value of the final product depends on inputs. The economics literature identifies three types of goods or attributes with respect to the way users can get information about them: search goods are those about which information is readily available; experience goods have to be tested before information on their characteristics can be

obtained and finally the quality of credence goods cannot be judge even after they have been consumed (Antle, 2001).

The problems resulting from asymmetric information were first discovered in investigations of leading causes for fluctuations in output and employment-large variations in the sales of new cars (Akerlof, 1970). In those investigations it was discovered, rather by chance, that the informational problems that exist in the used car market were potentially present to some degree in all markets. In some markets, asymmetric information is fairly easily resolved by repeat sale and through reputation. In other markets, asymmetric information between buyers and sellers is not easily resolved and often results in serious market breakdowns. For example, in insurance markets the elderly have a hard time getting health insurance; in credit markets, (Hobill & Sanderson, 2017) small businesses are likely to be credit-rationed; and in the market for labor, minorities and women are likely to experience statistical discrimination because people are lumped together into categories of those with similar observable traits (Akerlof, 2002: 413). Asymmetries in information are prevalent in credence goods or attributes, and lead to important inefficiencies, as there are incentives for opportunistic behavior on the suppliers of such type of products leading to under provision of high quality similar to the market of lemons (Akerlof, 1970). In fact, more recent research on information asymmetry theory conducted on online marketing suggests that lemons could drive high quality items away from a market, leaving a dominance of poor quality goods (Scott, Gregg, & Choi, 2015). This situation is particularly critical when associated to input attributes that affect not only firms but society as a whole, as is clearly the case of food safety. The literature in food safety provision is on a dead end, as either it becomes possible to convert credence attributes into experience ones, through credible labeling, third party certification or some other regulatory mechanism, or profit maximizing firms will always under provide credence quality attributes (Antle, 2001).

When the credence attribute or input is critical for a processing firm, managers have to find ways around the information asymmetry, as otherwise firm's profitability may be hurt. Goldsmith (2004) suggest that for purposes of high risk mitigation or market up lift, managers in buying firms may engage in hard contract on products identity preservation to increase control over products characteristic, and example outside the food industry is the Intel chips. What this suggests is that in the case of critical inputs, firms actively pursue institutional arrangements to solve information asymmetries. Along with input's identity preservation firms may require some sort of insurance or certification that the inputs they are buying have the required characteristics, if firms upstream on the supply chain have buying power, as it seems to be the case of retailers in the US and EU (Kinsey, 2003), the costs of such guarantee may successfully be passed down to the seller. This creates a problem, however, for the former may retaliate and cheat whenever they think they can go along with it.

Resource Based View (RBV)

The resource-based view was proposed by Wernerfelt (1984) in his classic paper, where he analyses the firm from the assets it has available and suggests that firm's diversification and competitiveness may be associated to control over critical resources. These can increase the competitive position of the firm by: leading to barriers to entry, facilitate diversification and expansion, and by reasons for mergers and acquisitions. When revisiting the paper in 1995, Wernerfelt acknowledges contributions from Rumelt (1984), who provides an explanation for heterogeneous resource endowments, and Montgomery and Wernerfelt (1988) and Montgomery and Hariharan (1991) who incorporate transaction cost economics into the resource-based view. He suspects that future research in the field will focus on how firm's resource endowment translates into successful strategies.

In subsequent years, Locket and Thompson (2001) focus on the apparent rejection of the RBV by economist, insisting that this strategic management theory is closely associated to economics, namely to industrial organization from which the concepts were originally derived. They argue that path-dependency of firm's competitive advantage is an important contribution derived from the RBV and it should be more used in economics. The authors identify in the literature a number of points of tension, between the RBV and economics: the first relates to the concept of efficiency in resource allocation, which is not much used in RBV; second to economist the way strategic management researchers establish the relationship between resources and outcomes, is somewhat ambiguous (Prim and Butler, 2001); third hypothesis generation is tautological. However, Lockett and Thompson argue that economist willing to understand in more detail why some firms become more competitive than others, should consider using more concepts of RBV and identify four areas where this theory could provide insights into economics: new institutional economics; dynamic proprieties of RBV; explanation of radical changes in firms and RBV insights to anti-trust issues.

Another recent paper in this area tries to reconcile the RBV with the competitive strategy perspective formulated by Porter (1980). The authors propose and test a model comparing these two perspectives of strategic management, aiming at reconciliation of these theories to a more general causal logic for firm's success (Spanos and Lioukas, 2001). They find that both industry and firm effects are important in explaining firm's behavior and therefore call for more intensive use of both RBV and competitive strategy concepts in the identification of sources of firm's sustainability. In the RBV, resources are normally seen as assets that firms have and which ensure their competitiveness. To Wernerfelt (1984) brand names, in-house knowledge of technology, trade contacts, machinery, capital are all examples of resources. But he also seems to suggest that buying and/or selling power and access to specific resources can also be considered resources leading to competitive strategies in Porter's sense. Therefore, gaining information on a critical credence input seems to be a reasonable way to obtain competitive advantages using a RBV insight.

Transaction Costs Economics (TCE)

The sphere of influence of a firm, the role of prices on resource allocation and the coordination actions of the entrepreneur are discussed by Coase (1937). According to the TCE theory firms are a particular form of organization called a "hierarchy" for administering exchanges, or "transactions," between one party and another. This form (the "hierarchy") is then contrasted with "markets," in which transactions take place without managerial oversight (Coase, 1937; Williamson, 1975; 1985). At the heart of the TCE theory are three characteristics, namely, asset specificity, uncertainty, and frequency of interaction. Asset specificity is the extent to which the seller possesses unique proprietary inputs to the product/service being purchased. Uncertainty is the inability to predict future business conditions. Frequency is the number of times the buyer will make repeat purchases of the same good/service. Asset specificity and uncertainty are the two important dimensions of TCE, which lead to an increase in costs to the buyer of using the market. They are essential motivators for the drafting of protective contracts that are prompted by the likelihood of failures in the market mechanism due to friction in bilateral transactions between parties (Williamson, 1989). Firms therefore exist because they can reduce the costs of negotiating and are more effective than the market in resolving disputes that would arise from the exchange (Coase, 1937).

TCE theory has had great influence in economics and strategic management as it sheds light into firm's organization, reasons for vertical integration, buyer/sellers contracts, multinational enterprises, the role of managers and many other issues. Analyzing the extent to which vertical integration leads to better performance, D'Aveni and Ravencraft (1994) find that

strategic management researchers and economist have opposing views on the role of vertical integration in improving performance. The conflict seems to originate on the gains from efficiency assumed by economists and the increasing bureaucracy cost recognized by strategic management researchers. D'Aveni and Ravenscraft (1994) develop an empirical model to test three hypotheses emerging from this conflict: the first argues in favor of vertical integration posing it leads to lower costs and higher profitability; the second poses that vertical integrated firms face higher administrative and ratios of production costs to sales, and, last, the third relates demand uncertainty to higher costs in vertically integrated firms, when compared to non-integrated ones. In their model, they control for economies of scale and scope as they may generate noise on the hypothesis. They use data from 1976 Federal Trade Commission (FTC) line-of-business database, which they claim to be the only one suited for strategic and competitive advantage variables of interest. Their main result is that integration economies are more important than increases in costs due to bureaucracy, which seem to be mostly associated to higher production cost due to lack of market pressure. Forward integration seems to be more profitable than backward, the results were consistent across industries included in the FTC database.

In a more integrative paper, Madhok (2002) tries to reconcile two important theories of the firm, the transaction costs economics (TCE) and the resource based view (RBV). While TCE is mainly concerned with why firms exist, hence concerned in understanding the coordination through the market or through an authority with an organization, the RBV focus on each firm, and on its competitive advantage. After suggesting why there hasn't been any effort to combine the insights of TCE and RBV, the author provides his main contribution: the triangular alignment hypothesis, in which the boundaries between the firm and the market and their competitive advantage depend not only on transaction costs (as suggested by TCE), nor on the resources (associated to he RBV), but on both of these and also on the governance structure. Madhok's main conclusion is that Coase's contribution is even more significant for strategic management when one recognizes the association between TCE and RBV and then adds the governance structure to these. There is already some evidence that both costs and skills matter, but there is still need for further research unifying these two theories.

Institutional theory

According to institutional theory, organizations are embedded in a social environment that is constituted by institutional rules and norms (Meyer & Rowan, 1977). These rules and norms represent expectations shared by the members of a society or industry about what constitutes "good" management and how an organization should be structured to be effective. When they eventually become established or taken for granted, these expectations then become accepted as norms that govern behavior, in other word, they become institutionalized. When that stage is reached, institutionalized norms and mores shape the cognitive processes of decision-makers by reducing many of the uncertainty surrounding such decision processes. (DiMaggio & Powell, 1983). Because of their emphasis on uncertainty reduction and the search for legitimacy, the assumptions of the institutional theory stand in contrast to those of the transaction cost economics theory whose emphasis is on economic efficiency and profits maximizing. The incongruity between the goals of efficiency and legitimacy has accepted in the extant literature since the pursuit of legitimacy often requires the adoption of practices that impede efficiency (Dacin, 1997; Meyer & Rowan, 1977). However, over the years, the scholarly literature has slowly been moving in the direction of accepting a convergence between the mandates of legitimacy and pursuit of efficiency goals (Dacin, 1997). Furthermore, deviation from institutional prescriptions is sometimes possible as organizational actors pursue their strategic interests, or

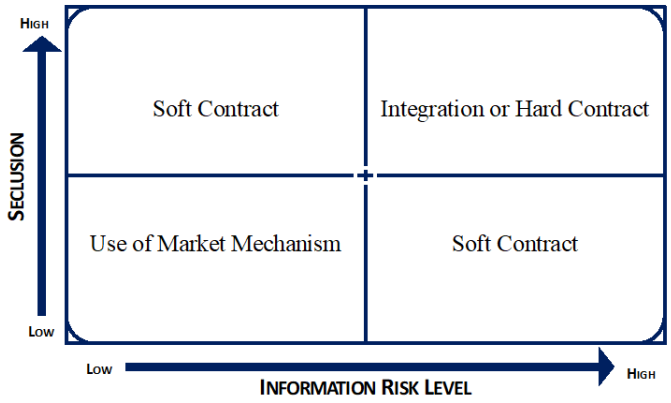
exercise discretion in ambiguous institutional contexts (Goodrick & Salancik, 1996; Oliver, 1991).

THEORETICAL DEVELOPMENT/MODEL

The literature on TCE and RBV will now be used to develop a construct for the analysis of the strategic formulation under asymmetric information on critical inputs. Throughout it will be assumed that the inputs or its attributes are credence in nature, meaning it is difficult and costly to assess the quality of the input even after its use. Furthermore, it will be assumed that firms at consecutive stages of a supply chain are heterogeneous and may take actions to improved credibility and reduce the level of information asymmetry if it improves their sustainability or competitiveness. One of the problems associated to asymmetric information is that it may to lead to a trap, for while information is a source of market power and therefore the rational decision maker, as described in the neoclassical model of economic, will seek rents to disclose it, under the circumstances considered in here retaining information may weaken the competitiveness of the firm with more information.

Asymmetric information increases the risk to the buyer of a critical input, especially in the case of credence inputs taken in here, as if the supplier opportunistically cheats on the quality of the product delivered, the product produced will under-perform, affecting the competitiveness of the buyer. Hence both the seller and the buyer of a credence input may improve their competitive position if they respectively disclose truthful information and engage in actions to increase their level of information on the product they buy to the other party. As Antle (2001) suggests the price mechanism fails when there is asymmetric information on credence attributes, hence some other institutional organization must be devised to solve this problem. One possibility is to vertically integrate, form some sort of partnership or contract with the seller, all of these clearly fall in the realm of TCE. Buying firms that are able to resolve the problem will control an important asset and improve their competitive position in the industry, the same can be said about those selling credence inputs, this competitive difference originates on assets of firms and therefore falls in the RBV explanation of competitive position.

Figure 1: Institutional arrangements: buyer/seller vs. information risk and seclusion



The discussion above proposes that firms selling credence inputs may improve their competitiveness by voluntarily disclosing private information on the characteristic and production process of the product they are selling. Also, depending on the risks associated to the product in question different institutional arrangements may be devised. Figure 1 suggests

such arrangements as the level of risk and seclusion (in the sense of non-disclosure of information) increases. The model is inspired on Goldsmith (2004), and identifies three different institutional arrangements.

In the context of this construct a soft contract is one where the parties retain control over their operations and penalties from breaking it do not severely hinder the position of firms. On a hard contract the parties agree on giving up some control over their operation, namely disclosing information that is relevant for the other party, a third party may inspect the quality of the information and severe penalties possibly leading to as much as the shut down of the business belonging to the offending party are included. Note that the market is not absent in this construct, in fact if there is easy access to information and low risks associated to the product or input being sold, transaction costs are low and the use of the market is justified. From this figure, several propositions may be derived, relating the strategic actions available to both buyers and sellers transacting a credence product subject to asymmetric information, with different levels of risk. We present the following three propositions, which are followed by a brief comment.

Proposition 1*: A supplier willing to disclose information on the characteristic and production process of the product it sells improves his competitive position by either having an easier access to market or to less strict contract forms.*

Given that at the core of the problem is an information gap, if a supplier voluntarily decides to disclose full information on whatever he is selling, it becomes less risky to deal with him and hence its opportunities are improved. In the food industry, the main causes of food safety hazards are well established and are associated to certain malpractices at the farm or processing levels, if information on these are made readily available then it become easier to prevent consequences of such actions. A firm in this industry that strives to always use the best practices and actively corrects errors and prevents accidents on the production process will certainly have a better competitive position than careless competitors. In such a situation disclosing information on its practices and allowing its clients to check how it is operating, will further extend a firm's competitiveness. In this sense, this proposition seems to be plausible and logical, as by adopting an open doors policy a firm becomes more trustworthy and will become a more attractive provider of inputs, where quality is associated with certain procedures. In consequence, this will improve the competitive position of the firm.

Proposition 2: *Buyers of high-risk inputs will avoid the market and use contract or even other complex institutional to have more control over information and avoid exposure to opportunistic behavior of sellers.*

Market transactions are necessarily anonymous in the sense that no relationship is established between buyer and seller, there is no guarantee that the same actors will ever meet again on a transaction. In this sense the seller as no incentive to disclose more information that the one provided by other participants in the market because it will be impossible to reap any rents from such action. When the product being sold has the characteristic under consideration here, the costs of transacting will be too high for a buyer. Hence, since sellers on the market have no incentive to offer more information than the one provided by peers, the only possibility to a buyer facing high risks on a critical input is to turn to other institutional arrangements. As Figure 1 suggests, a supplier in such circumstances will have to choose on being more open about the level information, face a harder contract form or simply abandon his operations. Buyers that are

able to establish contractual relations with firms downstream, will improve their competitive position as they will be less exposed to risks associated to under-performance of inputs.

Proposition 3: *A buyer that develops a method to obtain accurate information on the credence attribute, may improve his competitive situation.*

In the case that no seller is willing to accept a contract, a buyer that is able to develop a method to differentiate suppliers according to their level of risk will improve its competitive position. Investment of research and technology is one of the assets identified by Wernerfelt (1984) as a resource that leads to an improved competitive strategy. The question remains whether a buyer can really obtain the requisite information on a product in a neoclassic market if such a development is possible. The answer would be a rejection of the assertion since, by definition, all relevant information is readily available and costless for all participants. However, in real world markets, purchases often involve some sort of test to the product before a decision is made, for example car test drives are now commonly offered by most dealers. Therefore, it seams reasonable that a firm may want to test a product, specially a critical input, before a purchase, if such a test provides crucial information at a negligible cost, it will certainly have an edge to competitors using the same resource**.**

DISCUSSION

The propositions above may be criticized at several levels, for one they contradict a common practice in current business strategies, where firms kept as much information as possible from competitors, being they at the same or different tiers of the supply chain. In this sense, the propositions above, namely the first one, may be regarded as unrealistic. Another possible criticism is that opportunistic behavior will lead to just another form of problem, for buyers will have incentives to provide incomplete or even false information and still have their way. Also, it could be argued that by definition of credence attributes or goods, it is impossible to provide credible information on them, which severely limits the practicality of such construct. Yet there is some evidence that firms in the food industry do take strategic positions as those proposed on part 3, as the work of Golan et al (2004) suggests. She and her co-authors investigate the implementation of voluntary traceability systems (through which information on sources and characteristics of food are kept along supply chains) and find that firms sharing information improve their competitive advantage by reducing the risks and costs associated to food safety hazards.

Kinsey (2003) announces that a new paradigm or economic system in the food industry is emerging and changing the way information is shared, as well redefining ownerships and management styles. It is a fact that markets of all types of food are more and more differentiated and that globalization is creating enormous distances between producers and consumers of products. As these realize the consequences of such situation retaining information may severely hurt the competitive status of firms. Also, firms adopting systems for disclosing information seem to be getting a better positioning in the market, either by improving their image on the face of consumers or by acquiring more contractual opportunities, in the case of producers of inputs. It is interesting to note how the reality of markets appears to be solving the impasse suggested by theory. But further analysis is required in order to investigate whether there is change on then structure of the market, in the sense that the rules of the game are being revised so that previous best responses are no longer useful, or if nothing really changed and the uncertainty as shifted from the product to the level of information.

An important insight of the RBV, as suggested by Locket and Thompson (2001) is its dynamic proprieties. This certainly can be introduced on a model analyzing the propositions

above, as it seems reasonable to assume that by having more information some preventive measures currently used by firms to avoid consequences of critical inputs may no longer be required, leading to efficiencies and improved competitive position. Also, it seems important to study how disclosing information changes the position of selling firms in the market. An interesting ethical and socially responsible argument may be made here. Are firms realizing that in order to keep they position in the market they have to do the right thing just because that is the way it should be done? This will remain an open question, for it is out of the scope of this article, but it should be carefully analyzed and tested in future research.

CONCLUSION

'This paper contributes to the literature in strategic management when there is asymmetric information and risk in crucial inputs for the performance of firms. A real application would be the food industry, where unavailability of information on credence inputs may lead to severe food safety hazards. Economists analyzing the consequences and remedies of food safety, suggest that more efficient food safety hazards reduction would be achieve if firms were given the opportunity of finding the most appropriate method of meeting a certain level of performance.

While allowing more flexibility this solution places a burden on managers. TCE, RBV, and Institutional Theory are found relevant for the formulation of constructs, models or frameworks to approach this problem, for on one hand asymmetric information rises the costs of using the market and decisions on disclosing or hiding information affect the competitive standing of firms in the industry. The main contribution that this paper makes is proposing a model that relates the level of risk associated to the purchase of critical inputs to the disclosure of information on its characteristics and means of production. As the level of risk and seclusion of information increases buying firms will tend to engage in harder contracts with their suppliers to safeguard their position.

Three propositions are offered and briefly discussed in the paper. The first proposition is that sellers of inputs with credence proprieties will improve their competitive position if they are willing to disclose their private information on the product they sell. The second is that buyers of very risky inputs will avoid the market and engage on different types of contracts upstream. The third and final proposition is that buyers investing in methods to check the quality or truthfulness information on their seller's input will presumably improve competitive standings in the industry. Though the insights from both neoclassical economics and opportunistic behavior on TCE cast doubts on the validity of the propositions suggested, there is some evidence that the food industry is undergoing a paradigm shift and some firms voluntarily adopting institutional arrangements, such as traceability systems, that increase the levels of transparency on products characteristics. The question is whether there is really a change in the way relationships between firms are established in an industry, or if it is the quality and accuracy of information, rather than that of products, that is the new source of uncertainty in this industry. Future research would use the propositions offered here on a coherent model to prove their implications. The work of Goldsmith (2004) is another good starting point for such an effort. Then, the industries described on the case studies elaborated by Golan, et al. (2004) could come under closer scrutiny to investigate whether the proposition have empirical support.

Finally, with the proliferation of product information websites, it is appropriate to raise questions about their impact on firm profitability, consumer surplus, and social welfare. Recent studies have raised concerns about effect of information in the market place (Fernqvist & Ekelund, 2014; Markopoulos, Aron, & Ungar, 2016). One study has shown that it is actually the firms that are more able to take advantage of information availability especially from websites, reduce their own information investments, and increase their profitability. The same research found that the existence of these websites may actually reduce social welfare, which seems to

contradict the conventional belief that more product information is beneficial for buyers (Markopoulos, Aron, & Ungar, 2016). More research would bring additional light on this important revelation since if the stated goal of transparency and information availability is to maximize consumer surplus, then a Pandora's Box of ethical concerns might be opened by such findings. Indeed, it appears that ethical issues may be at the core of the evolution observed in the food industry, as there may be some moral or social responsibility positioning under the current trend of providing more information on the supply chain. If this can be confirmed then there is a real chance of a Kuhnian (1970) paradigm shift in this industry. Either way, more research is necessary to clarify the dynamic.

ABSTRACT

Cuba is a territory where having Internet access is luxurious and challenging. To understand Cuban Internet use by individuals, we conducted this exploratory, mixed methods study. Drawing upon digital citizenship and digital divide literature, we collected and analyzed survey data of 60 Cuban users. The Chi-square analysis shows significant relationships existing among age group, network type, durations per connection, and frequency, location and medium of access. The qualitative data analysis reveals that, although Cubans encountered both physical and social barriers to global Internet and national intranet, they valued the Internet capabilities of communicating and online knowledge acquisition. Practical and policy implications are discussed.

KEYWORDS: Internet, Intranet, Digital citizenship, User value, Mixed methods, Cuba

> "I enter the 12-digit user name and 12-digit password from my paper slip and wait. The operation fails. I type it in again. And then again. I realize I should have charged my laptop for this. Eventually the spinny wheel stops. I have been rejected. I enter my user name and password three more times, each time more determined…. I am not giving up. I have already come this far…..This is going to be the time. I can feel it. … I type in my 12-digit login and 12-digit password for what must be the 100th attempt. … Hemingway never wasted an hour wrestling with crappy Wi-Fi. I smash an ant crawling across my screen with my login paper…" [Reported from Havana, Cuba, 4/22/2016]

MOTIVATION: CUBAN PARTICIPATION ONLINE

The opening vignette is an excerpt from the *Fortune* news article written by Erin Griffith who expressed her frustration and anxiety during the one hour of trying to go online from a WiFi hotspot in La Rampa, a six-block long stretch of the 23rd street in Havana. During her 3-day trip to Cuba to report on former U.S. President Obama's historic visit to Cuba in April 2016, Erin Griffith observed that "People don't get on the Internet in Cuba... They 'go to Internet,' …" such as making trips to the limited number of Wi-Fi hotspots across the island country.

In a networked world where citizens of developed countries enjoy the affordable and ubiquitous Internet access and social media technologies, it's difficult to imagine a place on the Earth where getting online is not only a luxury but also a challenging experience. Cuba is such a territory. An estimate 5 percent of its citizens have access to the global internet and roughly 25 percent of the people have access to the Cuban intranet, based on the self-reported statements by Empresa de Telecomunicaciones de Cuba S.A. (ETECSA), government monopoly controlling cell phone, fixed phone and Internet markets in Cuba. This makes Cuba one of the least connected countries in the world (BBC News, 2016). Among the barriers to Internet access, high prices, exceptionally slow connectivity, and extensive government regulation have become the major hurdles to Cuban citizens to go online.

In 2015, Cuban government opened 35 public Wi-Fi hotspots in Havana and the rest of the country. Those Wi-Fi hotspots provided global Internet access. As of March 2018, there were 673 hotspots, 207 fixed navigation rooms, and 771 navigation areas in hotels, Joven Clubs, and post offices, according to the 2018 Informatica conference and trade show concluded held in Havana (http://www.informaticahabana.cu/). However, the daunting cost of access has prevented majority of Cuban citizens from having an Internet access. According to a BBC news report published in February 2016, the daunting cost for the slow Internet connection was $2 (£1.4) an hour, or about one-tenth of a Cuban's average monthly salary (BBC news, 2016). Although the cost was reduced to 1.5 CUC per hour (about $1.5) as of March 2018, the access to the global Internet remains slow and unreliable, at a maximum of 1 mbps due to radio and backhaul congestion (http://www.informaticahabana.cu/). Moreover, most citizens only have access to the national intranet, the internal network controlled by the state-owned telecom provider, ETECSA.

In this paper, we intend to address two questions: (1) how do Cuban citizens engage in the Internet technology? (2) do their behaviors of the technology use differ?

To achieve our research objectives, we conducted an exploratory study of Cuban Internet use from individual citizens' viewpoints. This research is informed by literature of digital citizenship, which we define as regular and effective use of digital network in terms of access and skills, consistent with prior research (e.g., Mossberger, Tolbert, and McNeal, 2007). We seek to understand individual Cuban's digital citizenship behavior associated the Internet technology. In particular, we view digital citizenship behavior as enactment of individual behaviors (in relation to *how, when, what* and *why*) in performing activities in the electronic network, including both the global Internet and national intranet.

We adopted a mixed methods approach, combining qualitative and quantitative analyses, which allowed us to explore linkages across variables systematically and to provide a rich account of user perceptions and backgrounds (cf. Mingers, 2001). Findings arising from this exploratory study are intended to provide insights into the emerging Internet adoption and use phenomenon in Cuba, and in furthering our conceptualization of information technology literacy in a different national context.

INVESTIGATIVE CONTEXT: CUBA INTERNET HISTORY AND CURRENT STATUS

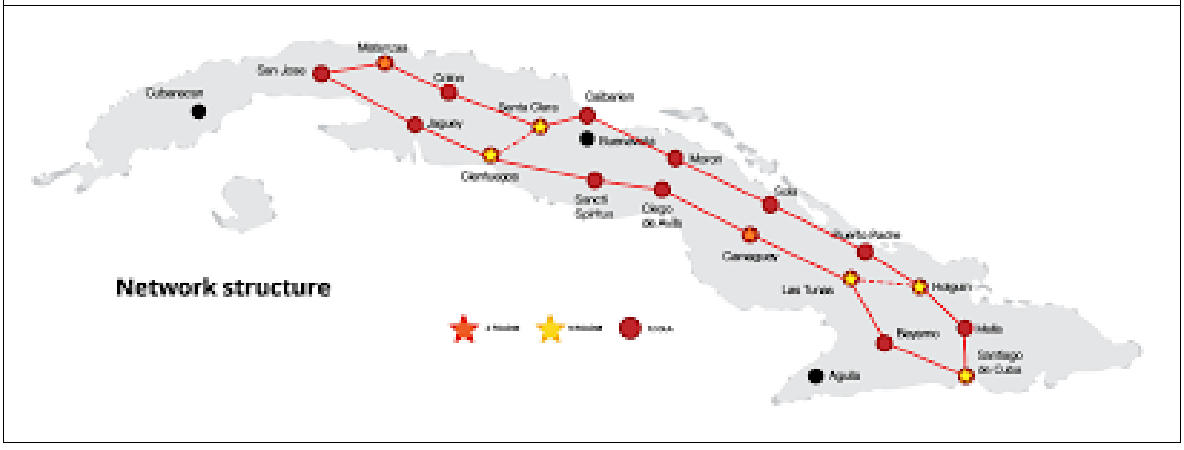
Three indices, the United Nations Development Program Human Development Index (HDI), the Freedom House Freedom on the Net score (FON) and the International Telecommunication Union ICT Development Index (IDI), establish context for the Cuban Internet. The HDI is a function of income, health and education and Cuba is the tenth ranked nation in Latin America and the Caribbean. FON is a function of obstacles to Internet access, limits on content and

violations of user rights and only five of 65 nations are rated as less free than Cuba. The IDI is a function of user access, use and skills. Cuba's IDI is ranked 135th of 175 nations.
Cuban policy emphasizes education and health care, which compensates for a relatively poor economy in determining their HDI and their emphasis on education drives the relatively high HDI skill component, offsetting low access and use ratings. According to the ITU's ranking of 175 countries, Cuba is ranked 135 in ICT Development Index (IDI), 167 in Access, 150 in use, and 57 in skills.

The sad state of the Cuban Internet is a product of its history. Cuba connected to the Internet shortly after the fall of the Soviet Union, which Raúl Castro and others thought was due in part to Soviet glasnost (openness). The Soviet collapse also triggered a Cuban economic crisis caused by the end of Soviet subsidy (Press, 2011). Bureaucracy and vested financial interests are believed to play a large role in Cuba's highly restricted global Internet access (Press, 2016a). In early 2017, ETECSA conducted a free home-connectivity trial in Havana by using the DSL technology, but challenges of the technology infrastructure persisted. As Press explained (Press, 2017a), the quality of a DSL connection is a function of the length and condition of the telephone wire running between a home and the central office serving it, thus requiring comprehensive planning and heavy investing by ETECSA in wiring as well as in central office equipment.

Today, the economy is hurting to a lesser degree because of the Venezuelan crisis. The Cuban government has learned to censor the Internet and use it for surveillance and propaganda, but bureaucratic greed and power within ETECSA, the state-connected monopoly provider, hold the Internet back (Press, 2016a). The image below shows the backbone network of the island nation (Nearshore Americas Report, 2015).

Figure 1. The Backbone Network in Cuba (Source: Nearshore American Report, 2015)



The Cuban Internet has opened slightly. The state-owned telecom ETECSA (http://www.etecsa.cu/) is one of the few government monopoly suppliers of Internet and landline and mobile telephone in the world. Over the last few years, they have created public access Wi-Fi hotspots. Home "broadband" service is now available in a small portion of Havana; there were 358 paying customers as of April 2017 (Press, 2017b). ETECSA is also conducting a 3G mobile trial in a small area. 3G has progressed significantly. Coverage is up and they are running trials in which any Cuban with a cell phone (as opposed to tourists and selected journalists and insiders)

can use 3G. Those trials are expected to end soon and 3G will be accessible to the general public in many places. Although it will still be slow and expensive, this would provide more access than Wi-Fi hotspots (Press, 2018).

While these efforts indicate a change in attitude and are of symbolic importance, they reach only a tiny part of the population and use obsolete technology. It is noteworthy that Chinese companies have been instrumental in much of this development. The most significant improvement in the Cuban Internet was the installation of an undersea cable connecting Cuba and Venezuela in 2015, but it is a strong link in a very weak chain leading to Cuban users. Google recently installed caching servers in Cuba and they will speed access to whichever services Google caches. As with the other measures, slightly better YouTube performance is of little value, but it may signify an important shift in Internet policy and policy on dealing with a US company.

We are also witnessing what may be somewhat more than symbolic changes in Internet-related applications and services. Cuba has legalized self-employment in 201 occupations, among them computer programmer (Press, 2017b). As of April 2017, there were 1,432 active, registered programmers in Cuba and the number has grown at an increasing rate every year since 2009, when there was only one. These people are doing contract programming (within and outside of Cuba) and developing services. There is also the beginning of a startup scene. The most recent indication of changing attitudes was a workshop intended to foster collaboration between the government software companies and independent software entrepreneurs.

As discussed below, prior studies have discussed the barriers to Internet access, information technology literacy, and the four kinds of access, all of which have provided us with useful insights when we explore and understand the Internet use and emerging digital citizenship in Cuba.

THEORETICAL BACKGROUND: DIGITAL CITIZENSHIP

Digital citizenship is defined as regular and effective use of digital networks, which depends upon having access and skills (e.g., Mossberger, Tolbert, and McNeal, 2007). The pervasive Internet technology in the U.S. and other developed nations has enabled communication and information dissemination online and contributed to the interactions between government and its citizens on electronic networks. All of these communicative functions are key aspects of the digital citizenship (e.g. Davis, 1999). In U.S. and other developed countries where Internet technology has become ubiquitous and governments use the Internet as an important channel to conduct their business (such as filing income tax and managing property tax), digital citizenship has been taken for granted. However, in countries that lag behind in information technology infrastructure such as Cuba, digital citizenship can only emerge with access to computers and digital networks.

Digital citizenship is affected by two types of barriers: infrastructural barriers to access and social barriers to access. First, infrastructure of digital networks includes computer hardware, software and network equipment for telecommunication network. At individual level, one good indicator is the computer ownership and usage. Researchers have referred the gap in computer ownership and usage as persistent indicator of a digital divide. The concept of the digital divide has, until now, been focused on “the gap separating those individuals who have access to new forms of information technology from those who do not” (Gunkel, 2003, p. 499). Lack of possession of a computer and a network connection is considered the critical factor contributing to digital divide. Second, social barriers to access refer to the access barriers arising from one’s social economics status (SES), including income, education, age, race etc. According to National Telecommunications and Information Administration’s reports (2000, 2002), income and

education are two of the SES that positively correlated with levels of access to and familiarity with computers and the Internet in the U.S. more than fifteen years ago.

Prior studies of digital citizenship and digital divide also suggest that digital divide led to information inequality, as Internet has become a major medium for information dissemination and information transmission. To further study the barriers to digital citizenship, van Dijk (2002) proposed a framework of four kinds of access. According to the framework, no possession of computer and network connection is only one of four kinds of access; other three kinds of access include: mental access (lack of elementary digital experience cause by lack of interest, computer anxiety and unattractiveness of the new technology), skill access (lack of digital skills caused by insufficient user-friendliness and inadequate education or social support), and usage access (lack of significant usage opportunities or unequal distribution of them). According to van Dijk (2002), framework of digital divide study contains a model of the four successive kinds of access.

Moreover, prior studies suggest that individual ability to take advantage of Internet access relies on the levels of information technology literacy (ITL) among them. For example, a study of 2002 Midwest urban random sample by Shelley et al. (2004) shows that interest in developing computer skills was positively associated with digital citizenship, and viewing technology as a source of informational power was positively related to support for computer access equity. As noted in the section above, Cuban computer skill is relatively high due to their emphasis on education.

RESEARCH METHODOLY: MIXED METHODS OF QUANTITATIVE & QUALITATIVE ANALYSES

Following Mingers (2001) and Mingers et al. (2013), we adopted a mixed methods approach – combining quantitative and qualitative analyses – to better understand the phenomenon under investigation. Quantitative and qualitative methods complement each other and have the potential to provide a richer exploration of the associations across variables (Mingers, 2001). In particular, we believe that this approach is appropriate for our investigation because there has been little sufficient evidence regarding individual Internet access and usage behavior in the Cuban context.

In conducting this mixed methods research, we followed the guidelines proposed by Venkatesh and colleagues (2013). Although relatively less frequently used in the IS field, mixed methods have been adopted by a number of IS scholars in their research, including Newell and Edelman (2008) in their investigation of effective mechanisms in cross-project learning and Deng, Wang, and Galliers (2015) in their exploration of customer-oriented citizenship behaviors by IS personnel. By combining quantitative and qualitative analyses in this study, we hoped to better understand the emerging phenomenon of Internet use and digital citizenship in the developing country of Cuba, particularly from the perspective of the Cuban citizens themselves.

Data Collection

We designed and administered a national survey on cubava.cu, one of the most popular digital platforms in Cuba. Cubava.cu is a hosting service for blogs, which provide easy access to Cubans to access via the Intranet or Internet, and allow them to read and manage blogs with relative simplicity. "Reflejos" is the name of their blogging platform -- like Blogger.com or Wordpress.com. Cubans can create blogs there. We offered that survey on our co-author's blogging site.

We collected data by using the survey instrument that included both structured and unstructured questions on individual access to Internet and their experiences. Rather than directly asking what Cubans value most in Internet access and use, we asked them to share experience in accessing and use Intranet and Internet. In this regard, we followed Friedman et al. (2006) by employing the indirect approach, which helps to "engage people's reasoning about the topic under investigation" (ibid., p. 19). The survey also included questions about their Internet tenure (how long they had been using the Internet), Internet use (frequency of connection and duration of each connection), and their demographics (e.g., gender; age; geographic location/province).

The survey was well received, with the following comments being typical:

> "Interesting proposal you do. I'll promote it on my blog." [Dec. 1, 2016; User D]

> "Very good your intention! I already have the link published in my blog xxxx.cubava.cu I have filled the whole survey, to see what results brings us this." [Dec. 5, 2016; User M]

Sample Characteristics

Our data sample includes 60 users who responded to the key demographics questions and Intranet/Internet use questions. Half of the 60 users are still new to Intranet/Internet, with experience of 1-3 years, and majority of the newcomers had access to Intranet only. Only 12% of the users reported experience of more than 10 years. The distribution of use experience is: 1-3 years, 50%; 3-5 years, 12%; 5-10 years, 27%; more than 10 years, 12%. In terms of users' age, majority of them (58%) are 21-30 years old, followed by 23% of them in 31-40 years old group. The distribution in the remaining categories is: 14-20 years, 5%; 41-50 years, 7%; 51-60 years, 7%.

The dominant medium for Intranet/Internet access is desktop PC, as reported by 85% of the users in our data sample. Only 15% of the respondents used notebook or mobile phone to access Internet and Intranet. In addition, workplace remains the popular location for their Intranet/Internet, as reported by 72% of the respondents.

The Intranet/Internet use (in terms of frequency) seemed to distribute across multiple categories, ranging from several times a day to several times a week. Of the 60 respondents, 33% accessed the network almost on a daily basis, with the reminder in the following categories: several times a day, 25%; several times a week, 22%; once a week, 8%; a couple of times a month, 10%; once a month, 2%. Similarly, the duration time per access ranged from 15 minutes to 8 hours plus. The distribution of duration time per connection is: less than 15 minutes, 12%; 15-30 minutes, 10%; 30-60 minutes, 18%; 1-2 hours, 18%; 2-4 hours, 13%, 4-8 hours, 20%; more than 8 hours, 8%.

ANALYSIS AND RESULTS

Quantitative Analysis and Results

As most of the quantitative data we collected from the online poll is categorical data, we perform an Chi-Square Test on the relationships between two categorical variables, including demographics factor (age groups), user type (Intranet vs. Internet), and the three types of Internet use behaviors (years of experience, frequency of connection, and duration of a connection). The analysis shows that there is no relationship between age groups and frequency of access.

However, some kinds of significant relationships exist between age group and the network use measures: time durations per connection, access location, and medium for access.

First, 14-20 years old are more likely to show a frequency of access one a week than others (chi-square 2.5). Moreover, they are more likely to access from Center and University (Chi-square: 18.05) and home (Chi-square: 4.5), than others, and less likely to access from work than others (Chi-square: 2.15). This result makes sense as people of this age group are still attending schools and university and study centers and home naturally become their main access location for digital network. For those in 41-50 years, they are more likely to use notebook for access, compared to other age groups (Chi-square, 2.0167). For 31-40 year-olds, they are more likely to spend 30-60 minutes per connection, than others (Chi-square: 4.593).

We also analyze the associations between type of user (Internet vs. Intranet) and other access measures. The chi-square analysis shows that Internet users are less likely to have access frequency of several times a day (Chi-square=2.131) compared to Intranet users. Internet users are more likely to have access frequency of couple of times a month (Chi-square=2.61), compared to Intranet users. In addition, internet users are more likely to use mobile phone (Chi-square=5.853) and notebook (Chi-square=2.926) for access medium, compared to others.

However, we'd like to point out that, given the nature of the sample, we are unable to make further statistical inference based on this data analysis.

Qualitative Analysis and Findings: Barriers and Perceived Values of Internet Use in Cuba

Our research objective was to investigate how human actors interacted with information and communication technology, rather than to hypothesize or test cause-and-effect relationships. This is consistent with interpretive approaches to IS research (Galliers and Land, 1987; Walsham 2006). We asked our survey respondents open-ended questions on their experience with Internet connection. We analyzed the written narratives from the respondents by following the well-accepted qualitative research methods outlined by Miles and Huberman (1994). For example, we started with open coding and codes suggested by the technology acceptance model (TAM) literature and e-commerce studies, then revised codes as we refined and clarified our theoretical interpretation. Our analysis reveals Cubans encounter both physical and social barriers to Intranet/Internet use. In addition, the data analysis shows two aspects of ICT that are particularly attractive to Cuban citizens – communication and knowledge acquisition.

Barriers to Internet Use in Cuba: Physical and Social Barriers

When responding to questions about their Internet/Intranet experience, our informants overwhelmingly talked about the slow and cost network access and connection. One user provided a detailed account of the two major barriers to network access:

> "It is also known by all, that the payment rates are excessively high because they are equivalent to a very high percentage of the basic salary of our country and only to sail for 1 hour. It is incredibly absurd but it is what we have. What are we going to do! In addition to this absurdity, we also have against us the connectivity they give us because it is limited and very minimum because we only have 1 mega of Wi-Fi. Which means that if you only pay for one hour for the high cost of it, you can hardly do anything, because it is extremely slow." [Dec. 2, 2016 by User L]

Another respondents shared this frustration of slow network connectivity and high cost, as shown below:

> "[The Internet access] is still very expensive and for the average worker who lives on his salary. It is a bit difficult to be paying 50 pesos to have only one hour of connection that goes as water because of the slowness of it." [Dec. 1, 2016 by User R]

In a country where the purchasing power of the locals is a $25 per person per month, with $25 equivalent to 687 pesos in 2015 (Rapoza, 2016), it would cause a financial burden to many Cubans if they have to spend 50 pesos-out of their 687 monthly salary—on one hour of network access. Under this circumstance, some users adapt their network access and usage behavior, such as accessing to Intranet more frequently than to the global internet. In other words, for those who have both Internet and Intranet accounts, their access frequency differed by the two types of network. In general, their Internet access was less frequently than Intranet access, as shown in the following remark:

> "If it is Internet, I access almost once a month from the Nauta Wi-Fi or sometimes I go to the club 1, where there is a Nauta room. If it is intranet, I access a few times a week." [Dec. 1, 2016; User T]

Although experiencing the difficulties and inconveniences, some respondents expressed hope for an improved Internet environment in Cuba. The following remark reflects the hopeful thinking:

> "Well in my case I access sparingly, either by speed or by cost. They should do something with the cost because not everyone has the same facilities at the time of payment (I have seen people who have logged in once every six months). But, well, everything is in the possibilities of the Revolution so I hope that the systems of access to the INTERNET for all will gradually improve." [Dec. 1, 2016 by User N]

Personal Values in Internet/Intranet: Communication & Knowledge Acquisition

The respondents of the survey valued their access to the network (both Internet and Intranet). Yet, the access is multifaceted; it conveys different meanings to different users. For majority of the users, the communication enabled by Internet access is personally meaningful to them. It allows them to connect to the outside world. One explained:

> "It is important to gain access to the Internet (.com) and improve connection speed and data transmission, this is the twenty-first century and step that we takes us XXII."

For some, this Internet-enabled communication was experientially meaningful, as they experienced joy and excitement in connecting with friends and family members. This is reflected in the remark:

> "What I see in most people use it to communicate with family and friends, and research topics they are interested, leisure, music, entertainment, etc"

For some users, the Internet access enabled them to gain more knowledge and develop competence in their technology-related field, as a result of having exposure to useful resources and documentations online. This is evidenced in the following two remarks:

> "I really use the intranet more than the internet but it is a tool for me of work that helps me increase and exceed my knowledge." [Dec. 5, 2016; User C]

> "I access systematically to the internet, since I dedicate myself to the development of software, and really there it appears all the necessary documentation. In addition, I have a site in Cuba, xxxxxxx.cuba.cu, which I try to update systematically." [Dec. 1, 2016, User R1]

For an island country with the low level of Internet penetration, the communicative capabilities afforded by the Internet are meaningful. To some users, they view Internet access meaningful not only personally but also at the national level:

> "As long as I can connect, I think that the national intranet should be given free of charge and thus promote services for the technological development of the country, and give the programmers a place to put their jobs or to be provided with ADSL to create their own servers to generate content in the network that is very scarce." [Dec. 6, 2016; User R2]

DISCUSSION

The objective of the study was to explore and understand how Cubans are getting online. Our quantitative analysis shows that accessing to Internet remains costly and constrained by the technological infrastructure in Cuba. Digital citizenship in Cuba is still at its incipient stage. As the Chi-square analysis shows, younger generation (14-20 years) are more likely to gain access from study centers, universities, and home, and they are more likely to use mobile phone and notebook. Internet users are more likely to have access frequency of couple of times a month, and more likely to access using mobile phones and notebooks.

Our analysis of the respondents' narratives reflects Cuban's value of Internet access for communication and knowledge acquisition. This finding is consistent with those reported by Aida Zekić, in her ethnographic study of Cuban Internet use based on her interviews with 50 Cuban Internet users at nine Wi-Fi hotspots in Havana during September and October 2016. In her data analysis, Zekić found that more than 90 percent of the 50 informants used the Internet for communication purpose (such as making long-distance calls and using social media), followed by 40 percent of them using it for informational purposes, such as searching information for school and work related activities, and reading foreign and domestic news. Fewer informants (fewer than 20 percent) used the Internet for entertainment, such as watching sports and movies.

In our study, the perceived benefits of communication and knowledge source valued and shared by the Cuban citizens reflected their experience of empowerment. For example, most of the Cubans in our survey valued the network-enabled communication with their families and friends living in different places and countries, which was personally meaning to them. In addition, Cubans valued Internet as a useful source of knowledge, as those Internet users felt that they had improved their knowledge and gained competency in their field (such as software development) via accessing to the resources and documents online. In both cases, the respondents expressed a sense of empowerment as Internet access became personally meaningful to them and enabled them to become more competent. These cognitions of meaning and of competence reflect the two dimensions of empowerment discussed by Thomas and Velthouse (1990): empowerment via meaning and empowerment via competence. According to Thomas and Velthouse (1990), the cognition of meaning reflects the personal meaningfulness of

a job activity, and the cognition of competence reflects one's confidence about his/her skills and capabilities to do the work.

CONTRIBUTION, LIMITATION, AND NEXT STEPS OF THE STUDY

This paper reported an exploratory study of emerging digital citizenship in Cuba. The study contributes to digital divide literature by providing nuanced understanding of digital divide in the Cuban context. The digital divide has tended to refer to whether individuals have access to ICT. In Western contexts. Selwyn (2004) differentiates between 'access to' and 'use of' ICT, and considers the consequences of engagement with the technology. However, the notion of digital divide and digital citizenship has been become outdated in developed countries. For example, In their work of crowd access to and engaged in the Internet-enabled online labor market, Deng, Galliers, and Joshi (2016) extend this digital divide work by pointing to the power imbalances between platform providers and job requesters and those who rely on crowdworking as their sole or partial source of income.

Given the difficulties of collecting large-scale survey data in Cuba, we collected data from online polls posted on a blogging site. We emphasized that each person only completed the survey once, and used IP host to identify unique responses. As a computer in the network might be shared by multiple users, a potential bias exists in this sampling approach. Initial findings form this exploratory study should be applied to other groups of users with caution. However, we tried to mitigate this bias by emphasizing unique responses among the visitors to the blogging site. Moreover, as our objective was to understand user behaviors associated with network access and usage, eliciting responses from those who have Internet/Intranet accounts became appropriate for the study.

Next Steps for the research project: First, we plan to analyze data of the remaining questions and of the larger sample. Second, based on the findings of the larger data set, we seek to propose a model of factors influencing digital citizenship to be tested in a large-scale data collection including those having Intranet/Internet and those who don't.

CONCLUDING REMARKS

The International Telecommunication Union (ITU) published an annual report on "Trends in Telecommunication Reform" and in the 2015 edition, they defined four generations of telecommunication regulation, including: G1 for regulated public monopolies, G2 for basic reform of partial liberalization and privatization across the layers, G3 for enabling investment, innovation and access, and G4 based on integrated regulation. Cuba was not included in the analysis shown here because of insufficient data, but, if they had been, they would have clearly been a first-generation nation (Press, 2016b).

New information technologies have empowering impacts on a society. At the national level, Zheng (2007) examined the role of new information technologies, especially the Internet, in facilitating political liberalization and making government more open, transparent, and accountable in China. The study concluded that the Internet empowered both the state and society in China, and the interactions between the state and society over the Internet ended up reshaping both the state and society. It remains an open question if/how Cuba government will deploy the Internet technology to improve the digital citizenship of Cubans.

The aforementioned 3G mobile trial illustrates Cuba's need to leapfrog technology. The ITU estimated there would be approximately 6.1 billion smartphones in the world by 2020 when we would expect to see the first deployments of 5G mobile networks, which promise faster data transmission rates, increased coverage, and more (ITU, 2015). Ironically, Cuba began a highly limited 3G trial less than a month after the ITU agreed on 5G performance requirements. They should leapfrog landline and mobile technology, which will require leapfrogging infrastructure, ownership and regulation policy (Press, 2016b).

Cuban Internet access is gradually improving. According to a Reuter report published in October last year, the increased availability of Wi-Fi hotspots in Cuba made it possible for nearly half the population of 11 million to be connected online at least once in a year (Meneghini & Marsh, 2017). Given the relative expense of connecting to the global Internet, Cubans use it mostly to stay in touch with relatives and friends. The report further stated that, Internet access prices had dropped to the $1.50 hourly tariff by November 2017, but it still represented 5 percent of the average monthly state salary of $30. More recently, Cuba witnessed the transition of its top leadership, with the stepping down of Raúl Castro in April this year (Faiola, 2018). Cubans may have a reason to hope that the new generation of their leaders will make significant change in the island country's economic development, including more Wi-Fi hotspots and reduced cost of Internet access, so that Cubans' trips to visit a Wi-Fi hotspots in the island country become shorter and more affordable.

ACKNOWLEDGEMENT

We appreciated the support to the research project from Dean Joseph Wen at the College of Business Administration and Public Policy, California State University, Dominguez Hills (CSUDH).

ABSTRACT

Social determinants of health (SDoH) including economic stability, healthcare access, and education, impact specific disease conditions and contribute to geographic disparities in health outcomes. This study investigates geographic disparities in health outcomes across Florida by analyzing SDoH and health outcomes data, and guides the development of interventions for specific populations.

KEYWORDS: Social Determinants of Health, Health Disparities, Healthcare Data Analytics, Cluster Analysis

INTRODUCTION

How long children born today live depends on the country in which they were born. Life expectancy for children varies from 80 years in Japan to less than 50 years in some African countries. In Europe, middle-aged adults from the lowest socio-economic groups are much more likely to die than those in the higher groups. Eighty percent of all people with diabetes live in low and middle income countries (WHO, 2008). Air pollution was responsible for 4.3 million deaths globally in 2012. This accounts for almost 10% of deaths in low and middle-income countries, as compared to only 0.2% of deaths in high-income countries (www.who.int, accessed Oct. 30, 2016). In the United States, those who finish high school live about 5 years longer than those who do not finish high school (McGill, 2016). Disparities in health caused by socio-economic and other factors including education and environmental conditions exist between and within nations, and need to be reduced.

According to the World Health Organization, the definition of the Social Determinants of Health (SDoH) is “the conditions in which people are born, grow, live, work and age” and “the fundamental driver of these conditions.” (www.who.int, accessed Oct. 8, 2016) These can include the socio-economic factors and access to certain resources in one’s community, as well as the behavioral factors. Examples of SDoH include the quality of education and workplaces, cleanliness of food, water or air, access to health care, diet and exercise, access to social and economic opportunities, race, gender, and the presence of any physical hazards such as poor housing and toxins (www.healthypeople.gov, accessed Oct. 14, 2016). The five key areas of SDoH are economic stability, neighborhood and built environment, health and health care

access, education, and social and community context (www.healthypeople.gov, accessed Oct. 14, 2016).

Poor socio-economic conditions can create negative impacts on health. According to the World Health Organization (www.who.int, accessed on Oct. 8, 2016), a person living in lower socio-economic communities is twice as likely to contract diseases which might lead to premature death. People living in such communities have few family assets, poorer education, insecure employment, poor housing, a family in challenging circumstances, and less than sufficient retirement pension. These disadvantages can continue to worsen throughout life, and lead to lower life expectancy.

LITERATURE REVIEW

SDoH Areas

Key areas of SDoH include economic conditions, the neighborhoods and built environment, access to healthcare, education, social and community conditions in which people live. Examples of economic stability determinants are poverty, employment, food security, and housing stability (www.healthypeople.gov, accessed Oct. 14). A major factor in the economic stability of an individual is employment based earnings including work related health benefits, such as medical insurance, paid leave, scheduled leave, workplace wellness programs, child and elder care resources and retirement benefits. Employment can also increase financial security and allow people to afford healthier living conditions. However, the working poor—7.4 million US workers in 2006—do not earn enough to cover health necessities and they often do not have access to many health benefits (US Bureau of Labor Statistics, 2008). Socially disadvantaged groups are more likely to have health damaging working conditions along with poor quality living conditions due to lower pay and lower economic stability (Egerter et al., 2008).

Neighborhood and built environment includes access to healthy foods, quality of housing, crime and violence levels in the community, and environmental conditions, such as pollution and proximity to hazardous substances (www.healthypeople.gov, accessed Oct. 14). Hazardous substances might include lead paint, mold, dust, or pest infestations. Braveman et al. (2011) reported that the built environment of an individual also includes quality of services such as schools, transportation, health care, and jobs that influence the prospects people have to make a living for themselves and their families. Work can influence health in many ways, the most significant ones being the physical factors or the workspace. Such factors might include poor ventilation, high noise levels, and exposure to hazardous materials, which can harm health. Jobs that require high amounts of physical activity can put individuals at a greater risk for musculoskeletal damages. However, jobs with too little physical activity are at a much higher risk of heart disease, obesity, and diabetes (Warburton et al., 2006). Psychological facets of work can also influence health such as working overtime, which, according to Braveman et al. (2011), has been connected to injury, illness and mortality.

Health and health care access is defined as how easily one is able to access health and primary care and one’s level of health literacy or understanding of their health (www.healthypeople.gov, accessed Oct. 14). According to Braveman et al. (2011), having a greater health literacy is related to the level of education one has. By having a higher level of education, individuals have the opportunity to get better paying jobs with many health benefits. These individuals can access health care much easier than educationally and economically disadvantaged individuals.

The determinants of education in a community are literacy, access to early childhood education and development programs, the number of high school graduates, and the number enrolled in higher education (www.healthypeople.gov, accessed Oct. 14). Education can also relate to health literacy, or one's knowledge about their health and what is beneficial to them. Higher quality education can lead to higher health literacy and allows individuals to make more informed decisions about their health (Sanders et al., 2009). Braveman et al. (2011) reported that better education allows for individuals to have a larger spectrum of employment opportunities, which can greatly reduce the risk of poor health and higher mortality. It can also protect against the effects of stress. These individuals are also more likely to get jobs with better physical and psychological working conditions, more health benefits and higher compensation (Crissey, 2009). It is also shown that these individuals have greater personal control and will make better behavioral choices. Education has been underestimated as an important determinant of health.

The social and community context is the social cohesion, civic participation, discrimination, and incarceration levels in one's community (www.healthypeople.gov, accessed Oct. 14). For example, in communities when members express mutual trust with one another and are more integrated, they will experience lower homicide rates and less anxiety and depression cases (Phongsavan et al., 2006). Similarly, workplace environments that enable mutual support among co-workers can help to safeguard against physical and mental health problems. Increased social support and more social advantages can allow someone to perceive themselves as a part of a higher social status which can lead to educational fulfillment, which is an important determinant of health (Demakakos et al., 2008). Race is also an important part of the social context determinants of health. Intentional or unintentional discrimination based on race or ethnicity can limit an individual's potential, and therefore "perpetuates social disadvantage" (Braveman et al., 2011). African Americans and Latinos are more likely to be residents in these poor neighborhoods with inadequate opportunities, which can lead to adverse health effects (Rouse and Barrow, 2006). Race can also more directly affect health through the stress of racial bias and prejudicial experiences regardless of neighborhood, income, and level of education (Nuru-Jeter et al., 2009 Williams and Mohammed, 2009).

SDoH Research

There are two main areas of research in SDoH and health outcomes. These are the study of the impact of SDoH on specific diseases, and the study of geographic disparities in health outcomes. Researchers have studied the impact of SDoH on many specific diseases and found links between SDoH and specific disease conditions. Victorino and Gauthier (2009) found that children are more likely to have illness such asthma, migraines, or ear infections if their family is closer to the federal poverty level. In another study, Rossen and Talih (2014) found that neighborhood socioeconomic and demographic factors may explain disparities in weight among US children and adolescents. Heart disease and diabetes are leading causes of death in the United States. Saiz et al. (2016) in a state-wide study in Wisconsin found that food insecurity could contribute to poor cardiovascular health. Patel et al. (2016) found that financial stress and worry impacts adults with diabetes resulting in them not following the required treatments. Mental health, which is also a large problem in the United States, is significantly affected by SDoH (Sederer, 2016).

The other area of research is to study SDoH and geographic disparity in health outcomes. Hood et al. (2015) study geographic disparities by examining the relationship between SDoH

and health outcomes in the United States. Their research compares county-level data from all states based on the County Health Rankings (CHR) database (CountyHealthRankings.org). They developed a model in which 35 different SDoH are combined into four health factors: socio-economic factors, health behaviors, clinical care including access, and the physical environment. The model determines health outcomes (length and quality of life) by combining these factors. Genus et al. (2016) have also used the CHR data to study the SDoH that contribute to health disparity in eight states in the Mississippi Delta region. They found that Delta and non-Delta counties had some common SDoH (tobacco use, diet, exercise). But they also found that some Delta counties were different with respect to community safety and income. Based on these findings, specific interventions can be made to improve the health of the region.
This study also uses the CHR data to study SDoH to examine health disparities among Florida counties. The study hypotheses are discussed below.

HYPOTHESES, DATA AND METHODS

Braveman et al. (2011) identify four areas for further research in their review of SDoH. These include the need to: (1) monitor changes of SDoH and health outcomes over time to determine progress, (2) study SDoH and health outcomes of children to see how childhood experiences have consequences over time, (3) better understand how SDoH ultimately affect health through various pathways, and (4) evaluate a combination of interventions to improve health disparities. This study follows the recommendation of monitoring changes to determine progress over time. Based on this, the purpose of this study is to better understand the health disparities between the counties in Florida by analyzing key SDoH. For this, the study will first investigate changes in measures and rankings of health outcomes by analyzing county-level data over time (2012-2016).

Hypothesis 1: If there are no changes in measures and ranking of health outcomes in Florida counties over the 2012-2016 time period, then there are no changes in the SDoH over this period.

Many interventions to improve SDoH are being made in Florida. But the Florida Health Gaps report for 2015 (Catlin et al., 2015) still identified significant gaps in some SDoH. But these gaps are identified at the State level and not for specific counties. So this study will use the 2016 SDoH data to analyze and classify counties in Florida into clusters according to their health outcomes. These county clusters are not geographic clusters but groups of counties that have similar SDoH and health outcomes. The results will then be evaluated to identify what interventions are needed to improve the health of Floridians in these county clusters.

Hypothesis 2: If SDoH and health outcomes data can be used to create clusters of similar counties, then appropriate SDoH can be identified for each cluster to target for intervention and reduce health disparities in Florida.

Data and Methods

Since this is essentially an epidemiological study, it was focused on publicly available data. There are various sources of population health related data such as the World Health Organization (WHO), the Centers for Disease Control and Prevention (CDC), HealthyPeople.gov, HealthIndicators.gov, and CountyHealthRankings.org. Data sets from the CDC and HealthyPeople.gov were more disease specific and not relevant for the purpose of this

study. The County Health Rankings and Roadmaps (CHR) program (CountyHealthRankings.org) is a collaboration between the Robert Wood Johnson Foundation and the University of Wisconsin Population Health Institute. They annually publish data that includes different variables from various government and other sources that are most current. This includes various SDoH such as high school graduation rates, obesity, smoking, unemployment, and access to healthy foods. These SDoH represent health behaviors, clinical care, social and economic factors, and the physical environment. It also provides data related to length and quality of life. The data is provided for almost every county in the United States, and ranks the counties based on the impact of the SDoH on health outcomes. CHR has its own scoring method for ranking health factors and health outcomes based on SDoH data, and ranks counties based on their model. In this study the data related to all the counties in Florida were studied using appropriate data analysis and statistical methods and software. The study used 2012-2016 Florida Health Rankings Data from CountyHealthRankings.org. Data Analysis and Visualization Software (Tableau 8.3, www.tableau.com) and Statistical Software (JMP 13; www.jmp.com) and Excel were used in the analysis.

For the study of changes over time in measures and rankings of health outcomes in Florida (2012-2016), county measures and ranking data for Florida from CountyHealthRankings.org was used. The individual annual measures and ranking data for 2012 and 2016 were combined into one data set. The data was reviewed to see how county measures and rankings of health outcomes changed over 2012-2016, and identify which health outcomes improved or declined over this period. Specifically, the 2016 SDoH and health outcomes data from CountyHealthRankings.org was then used to classify counties in Florida into clusters according to their SDoH and health outcomes. Cluster analysis was conducted to group Florida counties based on multiple SDoH and outcomes ranking data into clusters of similar counties. Data from Florida Department of Health, Division of Public Health Statistics and Performance Management (FLHealthCharts.com) was then further analyzed to understand the specific SDoH challenges in one of the clusters. The results were then evaluated to identify possible areas for interventions needed to improve the health of Floridians and reduce health disparities. Such a data based approach can help develop customized services to overcome healthcare disparities in different populations.

RESULTS AND DISCUSSION

The first hypothesis tested stated that if there are no changes in measures and ranking of health outcomes in Florida counties over the 2012-2016 time period, then there are no changes in the SDoH over this period. To determine whether or not there were changes in measures and rankings, the difference in health outcomes from 2012-2016 was used. First, the overall rank of the counties in health outcomes showed that 28 of Florida counties had become worse in health outcomes over this period, 31 Florida counties improved, and 8 counties experienced no change. When testing the measures of specific health outcomes over time, the health outcome with the largest overall improvement was the percent of adults that report poor or fair health, with 41 counties having improved measures, 17 counties with worsening measures and 9 counties that experienced no change. The health outcome with the largest overall worsening was the number of premature deaths, which is the number of deaths before the age of 75, and the average number of reported mentally unhealthy days per month. However, data that is a count tends to be more accurate than percentages and the number of poor health days reported because these are based on sample data, or data from a sample of a population and include sampling error. Also, because the percentage of poor or fair health and poor health days are only based on reported data, it does not take in to account the unreported fair or poor health

cases. As shown in Table 1, there is a worsening of health outcomes in counties for the number of premature deaths and for mental health. This is also shown in Figures 1 and 2.

Health Outcomes Ranks and Measures	Number of counties that have worsened	Number of counties that have experienced no change	Number of counties that have improved
Health Outcome Rank	28	8	31
Number of deaths under the age of 75	50	1	16
Percent of adults that report fair or poor	17	9	41
Average number of reported physically unhealthy days per month	28	7	32
Average number of reported mentally unhealthy days per month	44	5	18
Number of low birthweight births	26	1	40

Table 1: Change in Health Outcomes Ranks and Measures between 2012 and 2016

In addition, the 2016 SDoH county rankings of Social and Economic factors and Health Behaviors were statistically significant, while the county rankings of access to Clinical Care and the Physical Environment were not significant, as they related to the county Health Outcomes rankings (see Table 2).

	Coefficients	Standard Error	t Stat	P < 0.05 * significant
Intercept	-4.2384	3.2657	-1.2978	0.1992
Health Behaviors	0.5270	0.0801	6.5774	0.0012E-05*
Clinical Care	-0.0644	0.0801	-0.804	0.4245
Social & Economic Factors	0.5658	0.0701	8.0653	0.0031E-8*
Physical Environment	0.0963	0.0564	1.7081	0.0926

Table 2: 2016 County SDoH and Health Outcome Rankings Multiple Regression Results

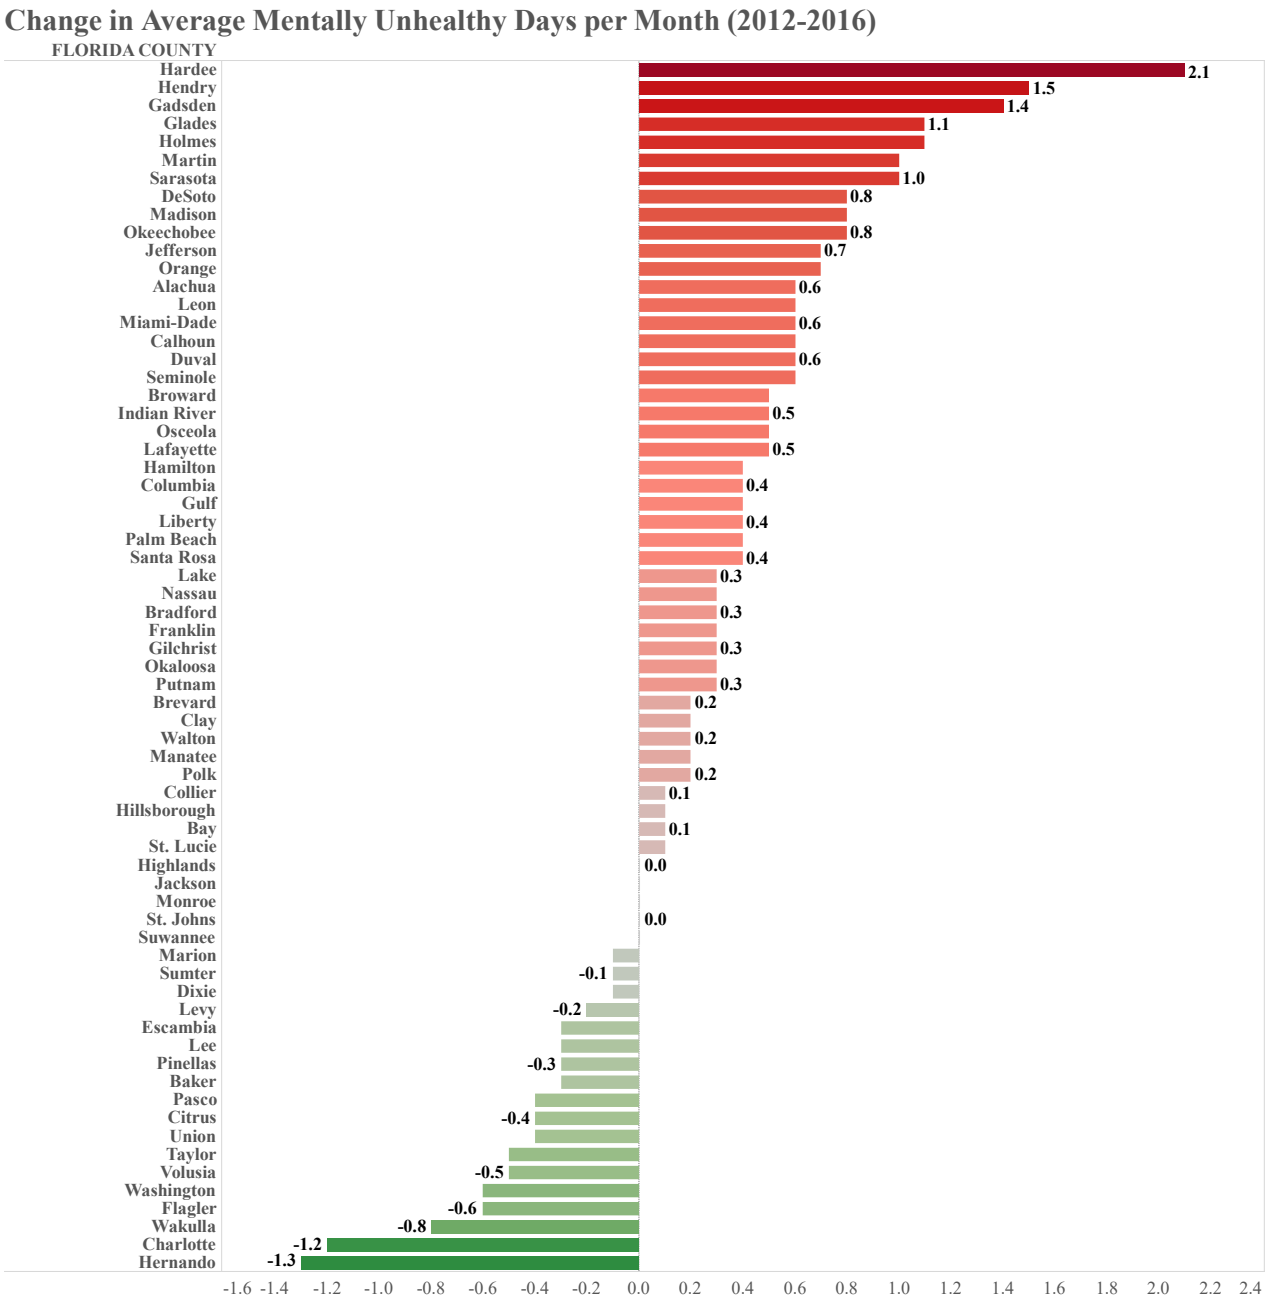

Figure 1: Change in Average Mentally Unhealthy Days per Month (2012-2016)

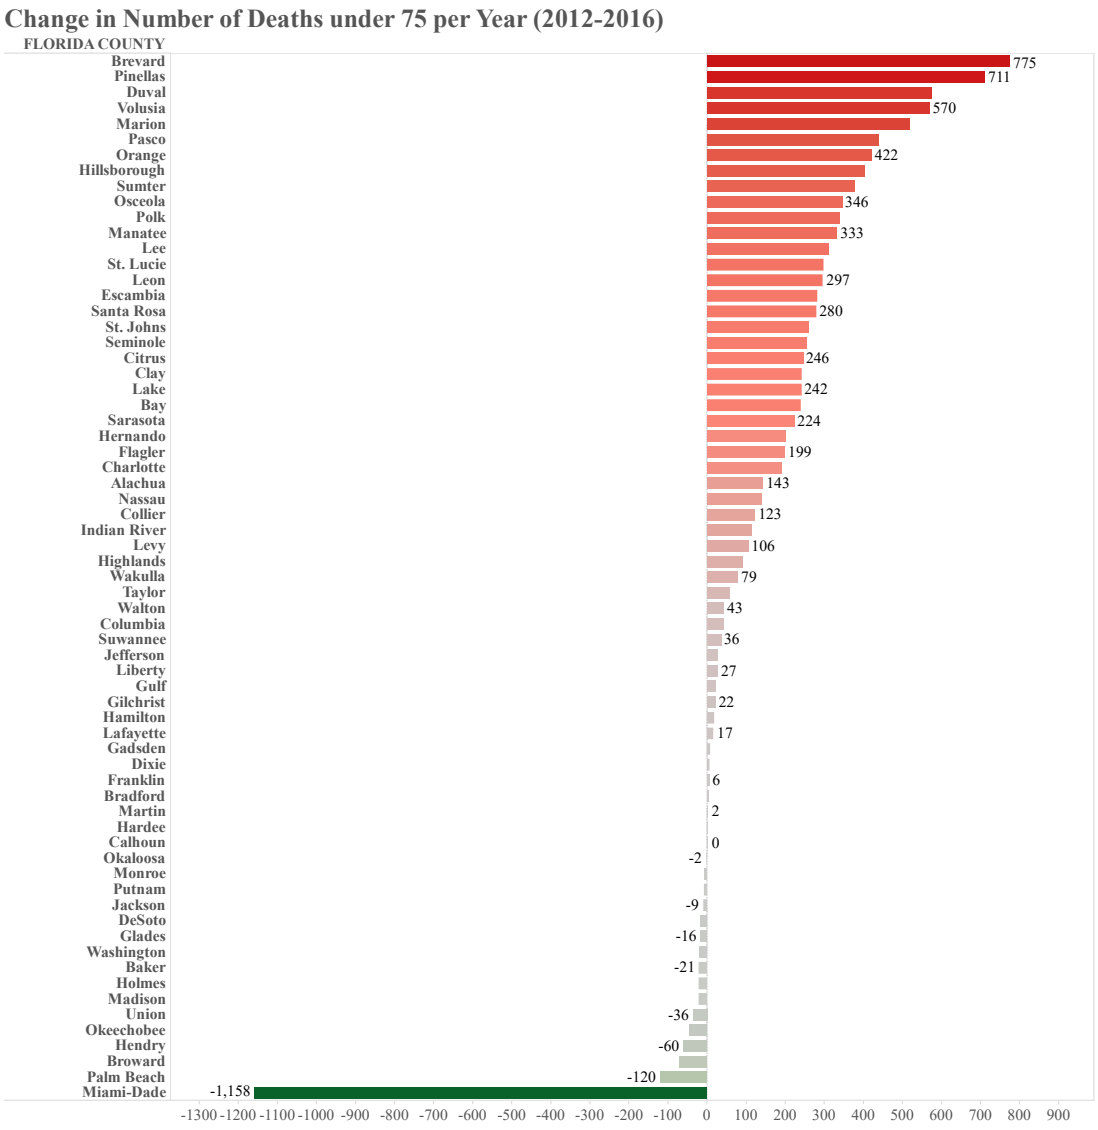

Figure 2: Change in Number of Deaths under 75 per Year

The second hypothesis tested stated that if SDoH and health outcomes data can be used to create clusters of similar counties, then appropriate SDoH can be identified for each cluster to target for intervention and reduce health disparities in Florida. The statistical software JMP was used to do cluster analysis. Cluster analysis is a technique of grouping rows of data (counties) together that share similar values across a number of variables (health outcomes and SDoH factors, ranks, and measures). It is a visual and exploratory technique to help understand the clumping structure of a data set. Hierarchical clustering was used and the resulting 7 clusters are shown in the constellation plot in Figure 3 below.

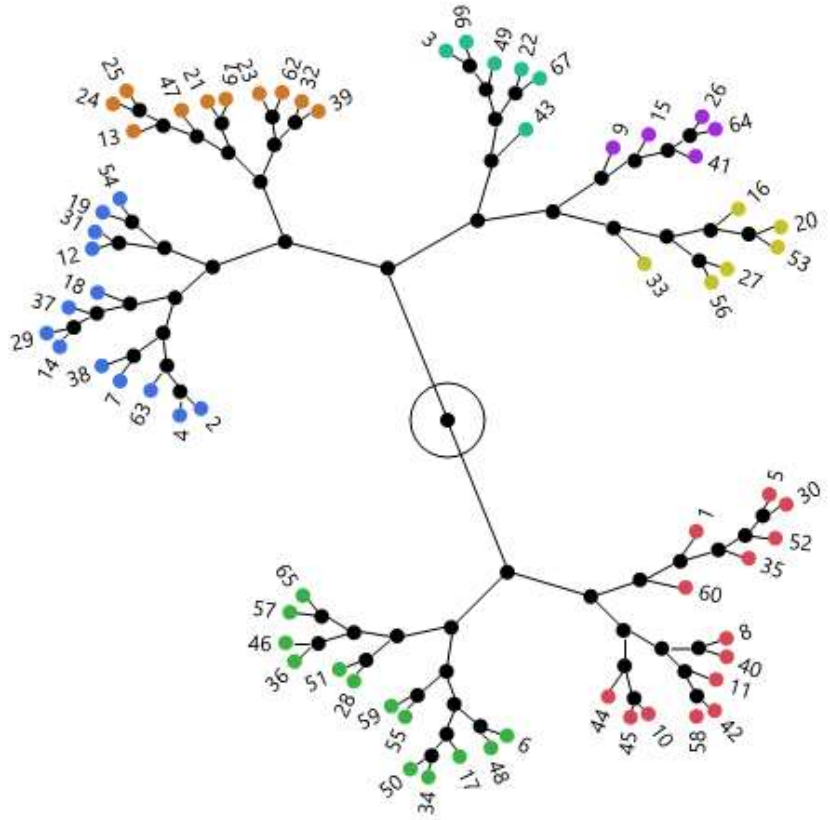

Figure 3: Constellation Plot for Cluster Analysis of Florida Counties by 2016 Factors and Outcomes Ranks

The counties corresponding to the clusters were identified from the data set. Then, the highest average rank SDoH factor was determined for each cluster. These are identified below in Table 3 for each of the related clusters of counties in Florida. These can be used for targeted intervention to reduce health disparities in Florida.

Cluster Number	Counties	SDoH with highest average rank
1	Alachua, Brevard, Charlotte, Clay, Collier, Indian River, Lee, Manatee, Martin, Monroe, Nassau, Pinellas, Sarasota, Sumter	Social & Economic Factors (education, employment, income, family & social support, community safety)
2	Broward, Flagler, Hillsborough, Lake, Leon, Okaloosa, Orange, Palm Beach, Pasco, St. Johns, Santa Rosa, Seminole, Wakulla	Physical Environment (housing, transit, air & water quality)
3	Baker, Bradford, Calhoun, Columbia, Dixie, Franklin, Gadsden, Holmes, Jackson, Levy, Liberty, Putnam, Union	Health Behaviors (tobacco use, diet & exercise, alcohol & drug use, sexual activity)
4	DeSoto, Glades, Hamilton, Hardee, Hendry, Jefferson, Madison, Okeechobee, Suwannee, Taylor	Social & Economic Factors (education, employment, income, family & social support, community safety)
5	Bay, Gulf, Miami-Dade, Osceola, Walton, Washington	Physical Environment (housing, transit, air & water quality)
6	Citrus, Duval, Hernando, Marion, Volusia	Social & Economic Factors (education, employment, income, family & social support, community safety) Physical Environment (housing, transit, air & water quality)
7	Escambia, Gilchrist, Highlands, Lafayette, Polk, St. Lucie	Clinical Care (access of care, quality of care)

Table 3: Key 2016 Social Determinants of Health by County Clusters in Florida

Further analysis could help in developing specific interventions in any county. For this Cluster 4 (see Table 3 above), which includes DeSoto, Glades, Hamilton, Hardee, Hendry, Jefferson, Madison, Okeechobee, Suwannee, Taylor counties, was further analyzed using detailed sociodemographic data from the Florida Department of Health. A two-tailed paired t-test indicated that percentage in poverty, percentage unemployment, and percentage poorly educated adults were all significantly higher than the overall State averages (Table 4). So poverty alleviating interventions would greatly help these counties improve their population health outcomes.

Socioeconomic Indicators	Cluster 4 Mean	FL Mean	P < 0.05 * significant
Percentage of individuals below poverty level	23.74	16.1	0.0012*
Percentage of families below poverty level	18.72	11.7	0.0006*
Percentage of individuals under 18 below poverty level	33.61	23.3	0.0058*
Percentage of civilian labor force which is unemployed	10.7	8.4	0.0082*
Median household income	36431.8	48900	0.0049E-04*
Percentage of 25 years and over with no high school diploma	25.61	12.8	0.0082E-02*
Percentage of population 5+ that speak English less than very well	9.67	11.7	0.4492
Median age (in years)	40.48	41.6	0.3820
Percentage of adults with health insurance coverage	81.13	83.6	0.2264

Table 4: 2012-2016 Socioeconomic Indicators for Cluster 4 Counties

CONCLUSIONS

The purpose of this study was to investigate geographic disparities in health outcomes across Florida counties by analyzing key SDoH and health outcomes at the county level. The initial analysis of the health outcomes data showed significant changes in two areas at the county level. It showed that health outcomes have worsened in many counties for the number of deaths before the age of 75 and for the average number of reported mentally unhealthy days per month. This does not support Hypothesis 1. So we conclude that the significant changes in county health outcome measures between 2012 and 2016 indicate changes in SDoH over this time period, with negative impact on health outcomes. So we must intervene to improve SDoH.

The second part of the study was to determine what SDoH areas need to be improved to positively change health outcomes for each county. For this, 2016 county data was analyzed and results supported Hypothesis 2. Clusters of similar counties based on SDoH and health outcomes were created. These clusters were evaluated to see which SDoH factor had the highest average rank (poorest performance) for the cluster. This helped identify appropriate SDoH for each cluster so that appropriate interventions can be used to improve health outcomes and thereby reduce health disparities in Florida. Further analysis using Florida State Department of Health data of a specific cluster of counties that had social and economic factors as the most significant, found that poverty and adult education should be specifically addressed to improve health outcomes in these counties. In this way, more detailed data analysis can help develop specific recommendations such as anti-poverty, anti-smoking, or diabetes prevention programs for a particular cluster of counties or a specific county.

This study was based on secondary data that was collected from many sources that are not always most recent. For example, the 2016 factors and outcomes data set was made up of data from other sources. While it used the latest available data, that data could have been from 2010 or 2014. This results in systematic errors that are caused by the environmental condition of data availability. Also, some of the information was reported data and would have errors in how people reported that data. The comparison of 2012 and 2016 outcomes was conducted in a basic fashion. This would introduce random errors because the difference was not statistically tested. But the clusters were formed through hierarchical cluster analysis. The technique is not perfect and so there is some random error that is introduced. It was statistically measured and

the clusters formed explained about 75 percent of the variation of the SDoH factors and health outcomes data.

This study identified two major health challenges in Florida: premature death before age 75 and worsening mental health. These are also challenges across the country today. The SDoH that drive these two health problems must be studied further. Understanding the SDoH for these at the county level will help us identify better interventions to overcome these health challenges, both in Florida and across the country. Healthcare is about both treatment and prevention. Improving SDoH is a very important and valuable way to prevent or reduce health problems in populations.

The study shows an approach to evaluate population health at the county level. It gives us a method to provide solutions to improve health outcomes that are specific to a community or region. By grouping similar counties, counties can also learn from each other's experience. That way, we can find what works and be able to improve health outcomes by improving SDoH. This method can also be used in other States in the country. By doing this at the county level, we develop a better understanding of the health and social needs of local communities. This approach can also be used across countries in the world. Such a study will help one country learn from another which would help improve global health.

ABSTRACT

This study aims at applying the expectation confirmation theory to explore how the friend factors affect on social commerce continuance intention, and further investigated the correlation between social media participation continuance intention and social shopping continuance intention. A total of 373 valid respondents involved in this study through an online survey. The findings demonstrated three antecedents of the related friend factors had a direct and indirect influence on confirmation, perceived usefulness, satisfaction, social media participation continuance intention and social shopping continuance intention. Social information influence was more effective than interpersonal trust and perceived friend's knowledge.

KEYWORDS: Social Commerce, Social Media Participation, Social Shopping, Perceived Friend's Knowledge, Continuance Intention

INTRODUCTION

In recent years, the rise of social media leads to online consumer behavior had profound changes. Aral, Dellarocas, and Godes (2011) indicated that social media is fundamentally not only changing our consuming, creating, communicating, and collaborating ways but also makes business activities changing revolutionarily. Enterprises tried to transfer online business activities from electronic commerce extend to social media, i.e., marketing activities of social media not only focus on good products, but also social relationship connection, interaction, and participation. Business model developed the so-called "social commerce."
Social commerce was a form of electronic commerce that comprises social participation and shopping activities via social media network (Liang and Turban, 2011). Most of the social network sites were working based on friendship (Trusov, Bodapati, and Bucklin, 2010). Compare with other formal reviews, positive or negative comments from friends are more influencial (Rad and Benyoucef, 2011), thus play an important role in the social shopping

process. Tang and Qiu(2016) examine these cross-platform impacts on content diffusion between different social media platforms. Although these platforms originally do not share information with each other, they are closely connected through users' cross-platform activities. Moreover, the effectiveness of information diffusion highly relies on well understanding the preference information of the targeted users. As users know more about their friends than marketers, the relations between the users become a natural medium and filter for message diffusion. Anderson et al. (2011) argue that "recommendations from the most influential people of all, the prospective buyer's friends and family" (p.1). Hence, social commerce needs to emphasize interacting with the shopper and friends.

Prior studies tried to involved social factors in electronic commerce and social commerce, for example, social CRM (Rishika et al., 2013), social influence (Bhattacherjee, 2000; Datta, 2011; Guo and Barnes, 2011; Lee, Shi, Cheung, Lim, and Sia, 2011; Li and Shiu, 2012), social tie (Wang and Chang, 2013; Wang et al., 2013), word of mouth (Kim and Park, 2013; Zheng, Zhu, and Lin, 2013; Wang et al., 2013, Awad and Ragowsky, 2008), social motivation (Guo and Barnes, 2011), social comparison (Hamari, 2013; Shen, 2012), online participation (Awad and Ragowsky, 2008; Casaló, Flavián, and Guinalíu, 2010), social value (Kim et al., 2011), social support (Liang et al., 2011), social interactive engagement (Pagani and Mirabello, 2011), user-generated social shopping features (Olbrich and Holsing, 2011). These studies focus on interaction with other online users, but social commerce needs to focus on interaction with shopper’s friends more than general online users.

However, most of the previous studies explored social commerce activities only focus on a single dimension to represent whole social commercial activities, such as Liang et al. (2011) and Zhang, Lu, Gupta, and Zhao (2014) explored the variable of social commerce intention only adopted to items of social media participation intention dimension to represent social commerce intention, and ignored the social shopping dimension. Thus, this study tried to fill this gap by exploring social media participation and social shopping dimensions, and the correlation between social media participation and social shopping in the context of social commerce.

Social commerce was a new business model of electronic commerce, and social media environment was a new platform for innovation that raises a variety of new and challenging research issues that require new theories (Liang and Turban, 2011). However, prior studies emphasized on individual perspective or interaction with other online users and lack of discussion about "friends' influence." Xu et al. (2014) indicated that peer influence was a critical factor on adopting new technology, and peer influence refers to as the influence of friends in the social network site. First of all, social commerce must focus on social perspective, especially the relationship between shoppers and friends. Previous studies tried to involved social factors, but related studies focus on interaction with other online members (weak ties) (such as Li and Shiu, 2012; Kim and Park, 2013); however, social commerce must emphasize on the interaction between shoppers and their friends (strong ties).

Kleiner (2011) demonstrated the influence of friends was very important in social commerce, 53% of consumers were willing to look up information about a brand if their friends had recommended it. Moreover, Crowdtap (2013) also showed that 41.7% of shoppers used social media to ask friends for opinions regarding a specific product or service via Facebook on purchasing holiday gift. Friends who have more related- shopping knowledge about specific product or service than shoppers their own, friends usually can facilitate consumer in shopping process (Mangleburg, Doney, and Bristol, 2004), and thus perceived friend's knowledge was a critical factor in shopping activities (Gershoff and Johar, 2006). Above, social commerce must emphasize the social perspective, emphasize interaction with one's friends (strong ties). However, prior studies emphasized on individual perspective or interaction with other online users, and couldn't not clear answer about the "friends' influence." This study tried to extend

expectation confirmation theory to explore friend's factor (interpersonal trust, perceived friends' knowledge, social information influence) how to indirectly influence on social media participation continuance intention and social shopping continuance intention in social commerce, and social media participation continuance intention between shopper and friend how to influence by social shopping continuance intention via social media. The research question includes the following:
Q1: How friend's factors (perceived friend's knowledge, social information influence, and interpersonal trust) might directly/indirectly affect social media participation continuance intention and social shopping continuance intention?
Q2: What kind of relationship might be between social media participation continuance intention and social shopping continuance intention in social commerce?

LITERATURE REVIEW

Expectation Confirmation Theory

Expectation confirmation theory (ECT) was a very famous and widely used theory in a lot of research field, as well as expectation confirmation theory developed based on the cognitive model of satisfaction decisions by Oliver (1980). The ECT model showed that consumer repurchase intention determined by the satisfaction factor of previous user experience, and the level of satisfaction also determined by prior confirmation or disconfirmation experience between expectation and perceived performance. ECT is majorly used to explore consumer behavior (such as satisfaction, repurchase, continuance intention, and post-purchase behavior) in the marketing field. However, Bhattacherjee (2001) found problems of ETC. Thus his study proposed a revised model to explore the information system (IS) continuance intention. The study indicated that perceived usefulness could replace post-adopted expectation. Secondly, the original testing time of ECT comprises pre-adopted and post-adopted, but the variables of pre-adopted also presented by confirmation and satisfaction of post-adopted. Thirdly, the post-acceptance model IS continuance pay attention to post-adopted expectation. The scholars of IS field had opportunity understanding and applying ECT to explore IS continuance usage behavior. Recently, the scholars of IS field still explore different new technology or information system continues usage behavior based on expectation confirmation theory. For example, Hong and Pavlou (2014) explored that product fit uncertainty is related to product returns, due to dissatisfaction based on expectation confirmation theory. Lankton et al. (2014) involved trust-in-technology into expectation disconfirmation theory to understand the trust how to influence the continued use of strategic information systems. This study also tried to examine how the friend's factor influences on social commerce continuance intention based on the post-acceptance model of IS continuance.

Social Commerce

Social commerce (SC) has been referred to "a subset of e-commerce that involves using social media, the online media that supports social interaction and user contributions, to assist in the online buying and selling of products and services" (Turban et al. 2012, p.305). Social commerce was a new business model, which was a form of electronic commerce, but social media technologies, interactions of communities, and commercial activities were different from electronic commerce. Thus, practice and academic field also do much research to understand the nature of social commerce. In recent three years, related studies tried to explore the each dimension of social commerce, such as social commerce concept and development history (Wang and Zhang 2012; Zhou et al. 2013), shopping flow (Kim et al. 2013), shopping motivation

(Pöyry et al. 2013; Guo and Barnes 2011), social tie (Wang and Chang 2013; Wang et al. 2012), social comparison (Hamari 2013; Shen 2012), word of mouth (Kim and Park 2013; Zheng et al. 2013; Wang et al. 2013), user-generated social shopping features (Olbrich and Holsing 2011), social interactive (Pagani and Mirabello 2011), social support (Liang et al. 2011). We found that prior studies had adopted different theories to explain the social media behaviors or specific phenomenon. However, the expectation-confirmation theory was not applied to explore social commerce continuance intention and related behavior. As the expectation-confirmation theory was suitable to explain this behavioral intention, it would be suitable to investigate consumers' intention in the context of social commerce. In addition, social factors were critical in social commerce environment. Previous related studies showed social factors only indicated the interaction between shoppers and other users or shoppers. However, this study reviewed that other scholars pointed out the definition of social commerce or research implications that found friend's role in social media was important. Thus this study deeply examined how the social factor-the shopper's friends indirectly or directly influence on social commerce behavior intention.

Social Media Participation and Social Shopping

The role of consumer participation initially began to receive attention in virtual community area (Casaló et al. 2010) and service marketing area (Cermak et al. 2011). Kang et al. (2010) pointed out participation is defined as "involvement in life situations and represents an interaction between an individual and the physical, social, and attitudinal environments." Social participation involves forming and maintaining social relationships and is supported by accessible environments and positive interactions” (p.1744). Zhang et al. (2014) pointed out participation behavior in social commerce includes requesting and sharing commercial information on social media. Pagani and Mirabello (2011) tried to explore the effect of social-interactive engagement and experiential personal engagement on active and passive behavior on social TV, and further study the advertising strategies of social commerce. Dholakia et al. (2004) explored that value perceptions on how to influence social influence (group norms and social identity), and indirectly impact on consumer intention to participation and participation behavior. They saw participation as "intentional social action."
Social shopping refers to "a method of e-commerce where shoppers' friends become involved in the shopping experience. Also, Kim et al. (2013) showed that social shopping “is a form of eCommerce based on social relationships in which friends influence each other’s shopping experiences and purchasing behavior on the Web” (p.170). Also, Ng (2013) indicated that intention to social shopping refers as “the perceptions and intentions to accept a friend’s product recommendation or review when purchasing a product on a social commerce site" (p.612).
From previous studies demonstrated that participation influences on shopping behavior viewpoint. Phang et al. (2013) demonstrated that higher levels of social media participation had significant enhance consumption intention. Casaló et al. (2010) also described that major outcome of online participation was the intention to purchase and adopt the products or services in the future. Maamar (2003) also pointed out consumers would ask their friends about the specific product before their purchase behavior. According to the discussion above, business activity viewpoint, purchase process viewpoint, and the participation influence on shopping behavior viewpoint, this study identifies two key consumer behaviors of social commerce were social participation and social shopping via social media.

Interpersonal Trust

Ng (2013) proposed the dimension of trust in social network community as "the sense of protection, care, and perception of reliability from the messages, feedback, or recommendations from other friends on a social network site." (p.612). Previous studies indicated that social media participation and social shopping intention significantly decided by trust construct. Pentina et al. (2013) presented trust on social media had a positive influence on continuance intention to use social media platform and provide some recommends to another member. Chu and Kim (2011) reported that consumers' become friends by having a mutual agreement and joining each other's social networks. Customers can review their friends' profiles, and thus social connections can enhance their credibility and social trust between the consumers and their friends. Their study also demonstrated that users trust their friends in the list of social network site; user perceived reliability and trustworthiness would directly significant affect their opinion seeking, opinion giving, and opinion expressing on social network site of social media participation.

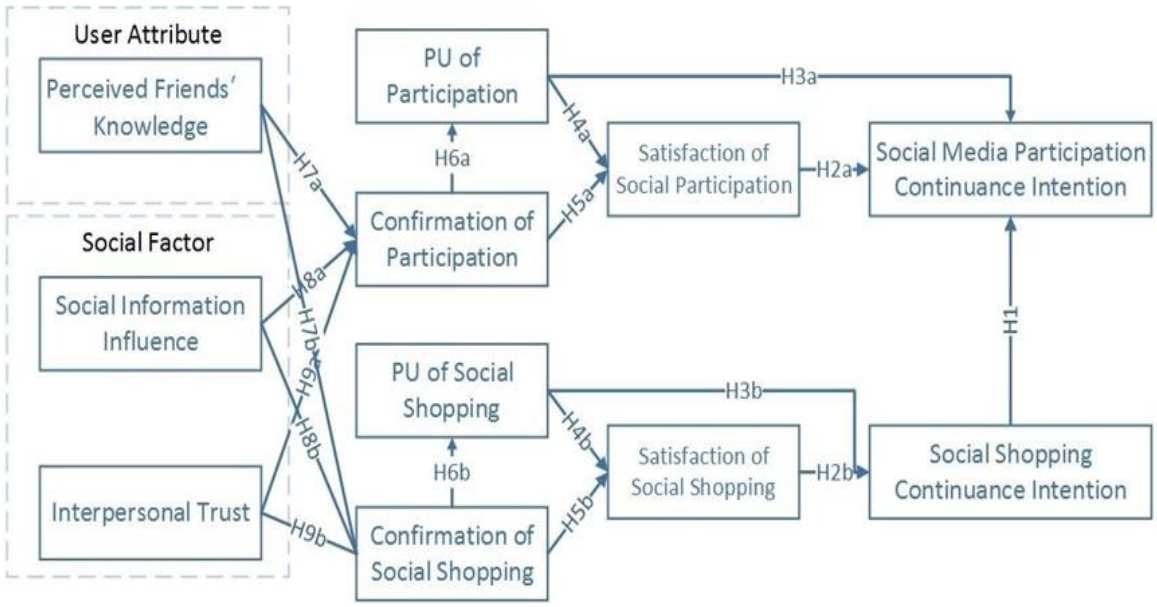
Social Information Influence

Informational social influence refers to “an influence to accept information obtained from another as evidence about reality” (Deutsch and Gerard 1955, p. 629). Kuan et al. (2014) indicated that informational influence was “one's tendency to conform to the opinions of others, based on information obtained as evidence in judgment" (p.154). Social information influence exists power in influencing social network behavior, and previous studies tried to involve social information influence to explore social network intention or social shopping behavior. Kuan et al. (2014) examined how informational and normative social influence on group-buying, and their study adopted brain imaging tools and self-reported to collect data. Wang and Chou (2014) indicated that group-buying repurchasing intention had indirectly significantly influenced by social influence. Risselada et al. (2014) explored the dynamic effects of social influence on adoption of high-technology products in a social network environment, and their study found social influence affected on adoption through different social influence variable. Ogara et al. (2014) adopted empirical study to demonstrate that social influence directly affects user's satisfaction with mobile instant messaging.

RESEARCH MODEL

According to previous studies, this study found friends of social media play an important role in social commerce environment. Therefore, friend's factors as antecedents would impact on shopper to confirm the prior expectation and post-adoption perception, and user's perception of system usefulness for social media participation and shopping via social media. Confirmation would directly affect user's perception of system usefulness and satisfaction with social media participation and social shopping. Next, the user's perception of system usefulness also affects satisfaction with social media participation and social shopping, as well as directly affects social media participation continuance intention and social shopping continuance intention. Based on expectation confirmation theory, interpersonal trust, perceived friends' knowledge, and social information influence literature, here is a research model showed in Figure 1.

Figure 1: Research model



Research Hypotheses

Social Media Participation and Social Shopping

Ng (2013) refers intention to social shopping as “the perceptions and intentions to accept a friend’s product recommendation or review when purchasing a product on a social commerce site” (p.612). Maamar (2003) pointed out online transaction context should consider about the relationship between shopping and friends, and such as pre-purchase phase, a consumer would ask the opinion of his or her friends about the specific product. Moreover, Pavlou and Fygenson (2006) demonstrated that intention to get information influenced by intention to purchase based on implementation intention theory. Also, consumers would like to visit social shopping via social media platform, because they can obtain product information, recommendation, and evaluation from friends of social media, and thus they go to social media platform to request their friends on social media. According to the discussion above, this study proposed the following hypotheses:
H1: social shopping continuance intention will influence social media participation continuance intention.

Satisfaction

Liang et al. (2011) pointed out "satisfaction is the degree to which a user is pleased with the overall experiences of using the social medium."(p.78). Hayta (2013) showed that satisfaction or dissatisfaction provides important opportunities for businesses to predict the buying decisions of other consumers. Satisfaction was a useful predictor of continuance intention (Xu et al. 2014; Zhou et al. 2014). Lin et al. (2014) pointed out satisfaction with social media had a strong correlation with continuance intention to use social media platform. Also, Huang et al. (2014) demonstrated that satisfaction with the seller had a significant direct correlation with two types of participation (positive rating and textual feedback submission). Pentina et al. (2014) also analyzed the previous empirical studies found one of the determinant factors of social media participation was satisfaction. Park (2014) demonstrated that continuance intention in social

network site was directly affected by satisfaction. When consumer had the higher satisfaction with social media, he/she would see the correlation with social media participation continuance intention and social shopping continuance intention. Therefore, this study proposal Hypotheses 2.
H2a: Satisfaction with social media participation will influence social media participation continuance intention.
H2b: Satisfaction with social shopping will influence social shopping continuance intention.

Perceived Usefulness and Confirmation

The concept of perceived usefulness was widely accepted in the information system field proposed by Davis (1989). Perceived usefulness be used to predict usage and measuring information system application. The definition of perceived usefulness refers to "the degree to which a person believes that using a particular system would enhance his or her job performance" (Davis 1989). Xu et al. (2014) also showed that perceived usefulness was theorized as the major antecedent of adopting intention or continuance intention. Previous studies demonstrated perceived usefulness has a directly significant influence on intention to shop through empirical data in social media environment (Hajli 2014; Han and Windsor 2011). Another according to a post-acceptance model of IS continuance, satisfaction was determined by perceived usefulness (Bhattacherjee 2001). Wang and Chu (2014) pointed out perceived usefulness had a direct influence on intention to research information in group-buying site. Zhou et al. (2014) examined social virtual world continuance intention; they used utilitarian benefit to represent the concept of perceived usefulness. Their study found perceived usefulness has an influence on satisfaction, and then satisfaction also has a strong direct influence on continuance intention by empirical data. Therefore, this study proposal Hypotheses 3 and Hypotheses 4.
H3a: Perceived usefulness of social media participation will influence social media participation continuance intention.
H3b: Perceived usefulness of social shopping will influence social shopping continuance intention.
H4a: Perceived usefulness of social media participation will influence satisfaction with social media participation.
H4b: Perceived usefulness of social shopping will influence satisfaction with social shopping.
Another, Xu et al. (2014) also presented that confirmation is a function to compare the difference between initial expectation and post-adoption; confirmation strongly affects perceived usefulness and satisfaction, and indirectly affects continuance intention. Based on the post-acceptance model of IS continuance proposed by Bhattacherjee (2001), the model presented confirmation had a significant and positive influence on perceived usefulness. Therefore, this study proposed Hypotheses 5 and Hypotheses 6:
H5a: Confirmation of social media participation will influence satisfaction with social media participation.
H5b: Confirmation of social shopping will influence satisfaction with social shopping.
H6a: Confirmation of social media participation will influence perceived usefulness of social media participation.
H6b: Confirmation of social shopping will influence perceived usefulness of social shopping.

Social Factor

Ngai et al. (2015) pointed out social factors were significant antecedents to predicate the social media outcome (such as user intention) through literature support. This study adopted

perceived friend's knowledge, social information influence, and interpersonal trust as three critical antecedents. Park (2014) pointed out customer perceived social network usage is usually affected by their close friends from a social network site. A popular application of social media also facilitates consumers to discuss, easily communicate, and self-disclosure among friends (Xu et al. 2014). When making a purchase decision, consumers often tried to obtain friends' prior purchasing experience, recommendations, purchasing evaluation, or product information. Gershoff and Johar (2006) indicated that a friend plays as an agent depend, and consumer decision relies on the friend's knowledge. Pentina et al. (2014) also analyzed the previous empirical studies found consumer knowledge had indirect influences on social media participation. Mangleburg et al. (2004) also found consumer perceived friends knowledge is better than the consumer, friends' knowledge (such as product, stores, brand, etc.) can facilitate the process of shopping for teen's group. Thus, consumer higher perceived friends' knowledge would increase correlation with higher satisfaction for social media. This study proposed the following hypotheses:

H7a: Perceived friends' knowledge will influence confirmation of social media participation.

H7b: Perceived friends' knowledge will influence confirmation of social shopping.

Recently, some studies tried to explore how social influence affect continuance usage in a social network environment (Xu et al. 2014; Kane et al. 2014). Wang and Chou (2014) pointed out "social influence is the extent to which social networks influence people's behavior through messages and signals from others that facilitate the formation of people's perceived value of a technology system."(p.122). Besides, Ogara et al. (2014) demonstrated social influence directly affect user satisfaction with mobile instant messaging. Dholakia et al. (2004) showed social influence (group norms and social identity) had an indirect influence on the intention of participation. Thus, this study proposed Hypotheses 8:

H8a: Social information influence will influence the confirmation of social media participation.

H8b: Social information influence will influence confirmation of social shopping.

Another, Lankton et al. (2014) showed that trust is related to satisfaction. Pentina et al. (2014) pointed out trust in social media site would have a direct positive influence on the intention to continue usage and social media participation. Liang et al. (2011) also showed that trust would have a significant indirect effect on continuance intention to social commerce. Ng (2013) pointed out trust had a substantial effect on purchase intention. Hajli (2014) demonstrated that trust had significant positive influence intention to buy in the social network site. Chu and Kim (2011) demonstrated that users perceived reliability and trustworthiness would have directly significant affect their opinion seeking, opinion giving, and opinion expressing on social network site of social media participation. Ngai et al. (2015) showed trust was one of the social factors that directly and indirectly affects personal intention. This study proposed the following hypotheses:

H9a: Interpersonal trust will influence the confirmation of social media participation.

H9b: Interpersonal trust will influence confirmation of social shopping.

RESEARCH METHOD

Questionnaire Development

This study adopted an online survey to collect data. All measures of each construct in Figure. 1 was adopted from previous studies and was measured using a 5-point and 7-point Likert scale. Questionnaires comprised of five parts: First, the title described the welcoming message, research purpose, subject requirement, data protecting strategy, incentive respondent strategy, and term explaining. The measurement variables of this study include: (1) independent variables: social factor (social information influence, interpersonal trust, and perceived friend's

knowledge); (2) mediating variables: perceived usefulness of social media participation, confirmation of social media participation, perceived usefulness of social shopping, confirmation of social shopping, satisfaction with social media participation, satisfaction with social shopping, and social shopping continuance intention; (3) dependent variables: social media participation continuance intention. This study used partial least squares (PLS) that was one of analyzing SEM technique that helped this study conducted the path analysis. The operational definition of variables, source, and the items see Table 1.

Table 1: Measurement of Variables

Variable		Operational Definition	Source
Independent Variable	Perceived friends' knowledge	Consumer feels the knowledge of social media friends that regarding product, shopping, or store.	Mangleburg et al. (2004)
	Interpersonal trust	Consumer perceived the level of confidence, beliefs and trust in the friends of social media.	Chu and Kim(2011)
	Social information influence	The consumer was obtained information from friends of social media, and then influence the shopping opinions, participate intention.	Mangleburg et al. (2004)
Mediating variables	Confirmation	Consumer confirmed the level of difference between expecting of pre-using and feel of post-using the social media participation and social shopping.	Bhattacherjee (2001)
	Perceived usefulness	Consumer feels the degree of useful and expected benefit with the functions of social media participation and shopping provided by the social media network.	Dang et al. (2014)
	Satisfaction	Consumer perceived satisfied, happy or pleased with social media participation related to shopping, and shopping via social media network.	Liang et al. (2011)
	Social shopping continuance intention	Consumer intended to continue shopping via social media network.	Bhattacherjee (2001)
Dependent Variable	Social media participation continuance intention	Consumer intended continuing social participation related shopping via social media network.	Bhattacherjee (2001)

Sample and Data Collection

This study adopted on online survey system to collect data. Subject must have social media participation and social shopping experience. This study total received 478 respondents; however, after data cleaning, this study removed 105 sample. Here are removing reasons: (1) never used social shopping or social media participation who have13 respondents; (2)19 respondents repeatedly fill the questionnaire. This study confirmed repeat e-mail respondents,

or if respondents did not write e-mail then check the fill time (similar time to check the answers, if the answers were the same, the respondents would be dropped); (3) 73 respondents were also dropped for outliers through box plot of SPSS analyzing. Finally, 373 respondents were involved in this study, and the effective response rate was 78%.

RESEARCH RESULTS

Respondent Characteristics

This study uses descriptive analysis to analyze subjects' demographics including gender, age, education, occupation, user experience (social media experience, social shopping experience, social media participation experience), and social media type (for using, for social shopping, and for social media participation) by SPSS 22 software. Table 2 showed the demographic analysis of 373 respondents.

Table 2: Demographic Analysis

Characteristics	Item	Frequency	Percentage
Gender	Male	133	35.7
	Female	240	64.3
Age	Under 20	24	6.4

Reliability and Validity Analysis

All measurement items were theoretically grounded and based on the previous studies; thus this questionnaire has face validity. In order to obtain the content validity of the measurement, this study invited seven experts to review items which include two practical experts, four academic experts, and one language experts. Before the formal test, the pilot test invited twenty social media users who have social shopping and social media participation experience to identify problems of the research design. Thus, content validity will thus ensure.

The questionnaire of this study was modified using the scales provided from previous studies (Bhattacherjee 2001; Chu and Kim 2011; Dang et al. 2014; Liang et al. 2011; Mangleburg et al. 2004). This research using Cronbach's α and composite reliability (CR) to measure the reliability of constructs. All the value of Cronbach's α and composite reliability (CR) were higher than 0.7. Hair et al. (2006) pointed out the sample size was above 350, the value of factor loading must higher than 0.3. The factor loadings of this study were above 0.7, representing the items were reaching statistical significance. These results indicated that the reliability, convergent validity, and discriminant validity were at an acceptable level, as reported in Table 3.

Hypothesis Testing

This study adopted SmartPLS technique conducting the path analysis. Two stages involved the structural model analysis. Using bootstrapping technique of SmartPLS 3 software to conducted the path analysis of the structural model, and then obtained the path coefficients and coefficient of determination. Figure 2 showed the results of path coefficients on every relationship. Table 4 pointed out the detail the path coefficients and p-value, and Table 5 also presented the R square (β) of the dependent variable.

Table 5: R Square of Dependent Variable	
Variable	R Square
Confirmation of participation	0.315
Participation continuance intention	0.660
PU of participation	0.466
Satisfaction of participation	0.424
Confirmation of shopping	0.236
Shopping continuance intention	0.562
PU of shopping	0.360
Satisfaction of shopping	0.451

Above, the results demonstrated that perceived friends' knowledge, social information influence, and interpersonal trust indirectly influence satisfaction (with social media participation and with social shopping) and continuance intention (social media participation and social shopping).

DISCUSSION

Analyzing results demonstrated that consumer perceived social shopping continuance intention had a positive and significant influence on social media participation continuance intention (β=0.387, $p<0.001$). R square of social shopping continuance intention was 0.562, and R square of social media participation continuance intention was 0.660. That represented social shopping continuance intention, and social media participation continuance intention had significant explaining power based on R square results. Analysis results showed the mean of social shopping continuance intention was 4.92 that represented the respondents almost fully agreed continuance intention to shop via social media. As well as the mean of social media participation continuance intention was 4.93 that also represented the respondents highly agreed continuance intention to social media participation related to shopping. The research results of Pavlou and Fygenson (2006) was similar to this study, which demonstrated the intention of getting information influenced by intention to purchase based on implementation intention by empirical study support. According to analyzing results, hypothesis 1 was supported.

Satisfaction with social media participation had a positive influence on social media participation continuance intention that support by data (β=0.2444, Satisfaction adopted the five points Likert scale, the respondents satisfied the social media participation (mean=3.56). Satisfaction was one of the significant predictors of continuance intention (Xu et al., 2014; Zhou et al., 2014). The results were similar to Lin et al. (2014), their study pointed out satisfaction with social media had a strong correlation with continuance intention to use social media platform. Higher satisfaction with social media participation indeed leads to higher social participation continuance intention that support by this study. The results were similar to Huang et al. (2014), and Pentina et al. (2014) demonstrated satisfaction had a positive influence on user participation intention (intention to submit a positive rating and intention to submit textual feedback).

The respondents perceived satisfaction with shopping via social media was satisfy, happy, and pleased (mean=3.55). R square of satisfaction with social shopping was 0.451. Satisfaction with shopping via social media had a significant and positive influence on social shopping continuance intention (β=0.419, $p<0.001$). Perceived social shopping satisfaction had a positive influence on social shopping continuance intention by this study supported. Consumers satisfied with the shopping playfulness and functional convenience of the previous social shopping

experience, and feel psychological happy and pleased that leads continuance intention to shop via social media platforms. The results were similar to the previous studies (Park, 2014 and Zhou et al., 2014). Therefore, hypothesis 2a and hypothesis 2b were supported.

Perceived usefulness (PU) of social media participation had a significant influence on satisfaction with social media participation (β=0.333, $p<0.001$) and social media participation continuance intention (β=0.331, $p<0.001$). R square of PU of social media participation was 0.466, and social shopping was 0.36. Mean of PU of social media participation was 5.07 and social shopping was 5.07.

Consumer obtained product information, group-buying activities, and store discount from social network friends, or given the comments for friends' shopping requests via social media platform. While consumers perceived the participation for shopping was usefulness, which leads to higher satisfaction with social media by data supported (Hypothesis 4a, $p<0.001$). The perceived social media could assist quickly to social media participation for shopping, such as collecting shopping or storing information, finding suitable requirement products, or real-time discussing with one's friends, and then influence social media participation continuance intention for shopping. Thus, analyzing results also supported that PU of social media participation had a significant influence on social media participation continuance intention (Hypothesis 3a, $p<0.001$).

Moreover, PU of social shopping also had a significant effect on social shopping continuance intention (β=0.422, $p<0.001$). The analyzing results also demonstrated that PU of social shopping positively influenced satisfaction with social shopping (β=0.351, $p<0.001$). The respondents perceived quick shopping via social media platform that assisted by social media functions and official website that enable consumers to order the product or service directly. Thus, the degree of satisfaction with social shopping was closer satisfaction (mean=3.55). The result of this study was similar to Awad and Ragowsky (2008) that presented perceived usefulness had significant influence intention to shop online. Analyzing the results of this study showed the respondents thought using the social media platform could enhance shopping effectiveness, and then, positive influence on satisfaction with social shopping. The result was similar to Casaló et al. (2010) study that pointed out PU would significantly affect satisfaction and responded Bhattacherjee (2001) pointed out satisfaction was a determination by perceived usefulness. Therefore, hypothesis 3b and hypothesis 4b were supported.

Confirmation of social media participation had a significant influence on satisfaction with social media participation (β=0.377, $p<0.001$). R square of confirmation of social media participation was 0.315. Furthermore, confirmation of social media participation had significant and positive influence PU of social media participation (β=0.682, $p<0.001$).

According to mean of confirmation of social media participation was 4.83, that represent the respondents perceived the service level by functions of social media participation for shopping was better than expected it. Using the experience of social media participation for shopping was better than respondents expected it, which lead to a significant influence on satisfaction with social media participation. Based on expectation confirmation theory, satisfaction positively influenced by confirmation. On the other hand, consumer perceived service or function level of social media participation was good, and that also directly affect perceived social media participation was usefulness. Thus, the results of this study demonstrated that confirmation of social media participation had statistically significant and positively influence PU of social media participation.

In social shopping part, the data also supported the confirmation of social shopping had a significant influence on satisfaction with social shopping (β=0.400, $p<0.001$). R square of confirmation of social shopping was 0.236. Mean of confirmation of social media participation was 4.68. Confirmation of social shopping also had a significant and positive influence on

satisfaction with social shopping (β=0.600, p<0.001). The results showed the experience of shopping via social media was better than originally expected, and the shopping service provided by social media was also better than expected (mean=4.68). This study also demonstrated the confirmation had a significant influence on satisfaction and PU by the expectation-disconfirmation theory proposed. The expectation of consumer was less than using the perception of shopping via social media, which leads to higher satisfaction with social shopping and perceived usefulness (such as enhances shopping performance, or shopping effectiveness via social media). Xu et al. (2014) also presented that confirmation likes a function to compare the difference between initial expectation and post-adoption, and confirmation strongly affects perceived usefulness and satisfaction and indirectly affect continuance intention. Therefore, hypothesis 5 and hypothesis 6 were supported.

Analyzing results demonstrated that perceived friend's knowledge had an influence on confirmation of social media participation (β=0.136, p<0.01), and perceived friend's knowledge had an influence on confirmation of social shopping (β=0.140, p<0.01). However, the statistically significant level and correlation coefficients between the relationship of perceived friends' knowledge and confirmation of social media participation, and perceived friends' knowledge and confirmation of social shopping were less than the relationship between other variables in this study.

Social information influence had positively and significantly influence on confirmation of social media participation (β=0.389, p<0.001), as well as social information influence had a significant influence on confirmation of social shopping (β=0.352, p<0.001) that supported by data. Mean of social information influence was 4.97. The results represent consumer often require the friends to help to choose the suit product, and obtain the product or service information or comments, or reference the prior shopping experience of user experience of friends. With social media had real time and quick search a lot of online friends, thus the respondents were willing to use the social media platform to communicate with friends than other communicate method (such as face-to-face, telephone, email). Social commerce was different from other electronic commerce. Consumers more care about friends' think than other members' comments of the network in social commerce. Therefore, consumers perceived friends' information influence ware high, and that lead to consumers perceive using experience, service level than initial expectation on social media participation activities and shopping via social media. Previous studies also had similar research findings.

Another variable of the social factor was interpersonal trust. The results also demonstrated that interpersonal trust had a positive influence on confirmation of social media participation (β=0.185, p<0.001) as well as interpersonal trust had an influence on confirmation of social shopping (β=0.119, p<0.05). Mean of interpersonal trust was 4.84 that represented the respondents trust the social media friends. Analyzing results showed the respondents trust most contacts on the friend's list of social media, and had the confidence to believe in the contacting friends of social media. From a statistical significant level, the interpersonal trust had a significant influence on confirmation of social media participation (p<0.001), then interpersonal trust influenced confirmation of social shopping (p<0.05). Pentina et al. (2013) also indicated trust on social media had a positive influence on continuance intention and provided some recommendations to other members. Also, Chu and Kim (2011) pointed out users trust their friends who in their friend's list of the social network site. Users perceived reliability and trustworthiness would significantly influence on their opinion seeking, opinion giving, and opinion expressing on social network site of social media participation. Therefore, hypothesis 7 to 9 were supported.

CONCLUSION

This study intends to apply the expectation confirmation theory to explore how the friend factors influence directly and indirectly on social media participation continuance intention and social shopping continuance intention, and further investigate the correlation between social media participation continuance intention and social shopping continuance intention. A total of 373 valid respondents involved in this study (valid response rate was 78%) through an online survey.

One of the interesting findings was social shopping continuance intention had a significant and positive influence on social media participation continuance intention. This study also demonstrated confirmation of social media participation had significant and positive influence on perceived usefulness of social media participation. The path coefficient is 0.682, which means after consumers participate in social media, the consumers perceived that social media participation is more useful than initially expected. The perceived usefulness of social media participation has become the most critical factor affecting satisfaction with social media participation.

In the social shopping section, confirmation of social shopping also had a significant and positive influence on the perceived usefulness of social shopping. The path coefficient is 0.600, which means after consumers shopping on social media, the consumers perceived that shopping on social media is more useful than initially expected. The results make the perceived usefulness of social media shopping has become the most crucial factor affecting social media shopping.

The perceived usefulness of social shopping also had a significant influence on social shopping continuance intention. The path coefficient is 0.422, which means that consumers perceive of using the social media platform are useful and can improve the shopping effect. For reasons outlined above, the perceived usefulness of social shopping is the most crucial factor affecting social shopping continuance intention.

Additionally, we also demonstrated three antecedents of related friend factors had, directly and indirectly, influence on confirmation, perceived usefulness, satisfaction, social media participation continuance intention and social shopping continuance intention, and social information influence was more effective than interpersonal trust and perceived friend's knowledge do. This study found perceived friends' knowledge, social information influence, and interpersonal trust were valuable variables in social commerce research.

This study has several implications to practice: For social media designers and vendors, friend's factor has a positive influence on social media participation and social shopping. The results showed social information influence affects indirectly social commerce continuance intention than other friend's factor (interpersonal trust and perceived friend's knowledge) does. Social media designers and vendors can design system function or mechanism for information exchange conveniently between shopper and shopper's friends. The results showed consumers like shopping via social media; they will go to the social media platform to obtain product or store information from friends of social media. Thus, designing the shopping functions creates the outstanding "interaction with friends" function. A consumer can merely see the friend's opinion of a specific product, or confirmation the online friends and then real-time talk with their friends to discuss the shopping questions.

For the marketing manager, the shopper's friends play an important role in social participation and social shopping. Thus, designing a marketing strategy can provide more social information, such as increase active alert about the friend's purchasing experience or friend's comments. Group- buying activities provide a friend's list of prior shopping experience on social media network and help shopper quickly look for the specific friend who had product knowledge or experience. For social media members, consumers understood how the personal social media

participation and shopping continuance intention influenced by friend's factors (interpersonal trust, perceived friends' knowledge, and friend's informational influence).

Research Limitation

Research design and implement were possible comprehensive in this study. However, three limitations still comprised of this study. First, this study adopted a cross-sectional study to investigate the research questions. Thus the results were not easy in-depth understanding of the relationship between independent variables, mediator, and dependent variables. Second, most of the respondents come from Taiwan, thus the results may not generalize to other cultures. Third, transnational respondents who cannot log in the Google survey system did not include this survey because the country had sent a limit of the specific network access.

Future Research

According to research limitations and results, above several research directions can provide a reference for future research. First, future study can adopt longitudinal study to deeply investigate the influence of friend factors (perceived friend's knowledge, interpersonal trust, and social influence), and understand the impact change of friend's factors in different time points. Second, future study can consider how different culture influence on social media participation and social shopping activities by friend's factors, due to social information influence was significant affects confirmation, then interpersonal trust and perceived friend's knowledge does in this study. Third, this study only explores continuance intention. However, previous studies also pointed out social media participation behavior would direct and significant social shopping behavior. Thus, future study can further examine behavioral relationship (social media participation behavior and social shopping behavior) by empirical study.

ABSTRACT

This research examines the relationship between social technology competence and digital collaboration among first-generation college students and their peers. To test our hypotheses, we collected survey data from a sample of 106 students in an urban 4-year university in the United States. The regression analysis showed that social technology competence had a positive effect on digital collaboration, and this positive effect is stronger for first-generation students. Our study contributes to the research on computer-supported collaborative learning and first-generation students, and offers insights into managing the social media technology practices at higher education institutions.

KEYWORDS: Social Technology, Competence, Computer-supported collaborative learning, Digital collaboration, First-generation students, Regression

INTRODUCTION

With the proliferation of social media (SM) technologies, academic institutions are increasingly using these tools for student outreach and student learning (Dabbagh & Kitsantas, 2012). SM technology refers to Web 2.0 technologies inclusive of social networks, blogs, wikis, multimedia platforms, and virtual worlds (Tess, 2013). In this paper, we refer to one's ability and skills with the use of SM technologies as social technology competence. Because SM technologies are tools that help users increase collaboration and gain a sense of community (Koch et al, 2013), users' competence with the social technologies of SM becomes important for them to achieve various outcomes. For example, college students may use some form of SM to create networks and stay connected with others. They use social media platforms for various activities ranging from socialization and communication to academic information search and information sharing. The benefits of SM such as Facebook on college students' academic work and college life have been evidenced in prior studies (e.g., Ellison et al, 2007; 2011).

Although most college students may have some pre-exposure to technology and resources such as social media technologies, others may not be so fortunate. While many students have been encouraged to attend college at a young age by their families where several generations have college degrees, there is another group of students with no family history of postsecondary

education. They are referred to as first-generation students, undergraduates whose parents' highest level of education is a high school diploma or less (Nunez & Cuccaro-Alamin, 1998). This population of college students faces economic, social, and cultural challenges in their college education. As first-generation students are from challenging economic backgrounds and are the first in their family to attend a postsecondary educational institution to attain a bachelor's degree, they are more likely to drop out of college compared to their better-equipped peers. For example, only 14 percent of low-income, first-generation students attending two-year institutions are eventually transferred to four-year institutions (Engle & Tinto, 2008).

Compared to their peers, first-generation students are generally older and less likely to receive financial aid from their parents. According to the study by Engle and Tinto (2008), 74 percent of low-income, first- generation students are financially independent. In addition, 30 percent of low-income, first-generation students are single parents and 38 percent have dependents. These first-generation students have many responsibilities to manage besides attending college: they may have to work outside of college or help take care of their families. This prevents them from accessing the full college experience, which explains why these students usually begin and end their postsecondary education at two-year institutions. When higher education institutions have a great concern for maintaining and increasing the college graduation rates, SM technology has the potential to offer various resources to a high risk population such as first-generation students.

The use of SM has been shown to have certain effects on the education of first-generation students. As suggested by Rahman, Ramakrishnan, and Ngamassi (2017), SM can bring the benefit of helping first-generation students improve learning outcomes at college. Another example of the SM impact is that first-generation students are more likely to use social media to search for colleges instead of relying on personal sources such as friends and family. For example, 27 percent of first-generation students discovered college on SM as compared to the 17 percent of non-first-generation students (Kelly, 2017).

However, little is known about the impacts of SM competence on first-generation students' digital collaboration for academic work. We refer to digital collaboration as the communication and collaborative activities enabled by digital technologies (such as social media platforms) for the purpose of getting help, consulting friends and classmates, and completing a joint learning task through social media. As many first-generation students spend a majority of their time working, they often do not have the time to fully participate in campus activities and obtain access to various academic support services (Eagle & Tinto, 2008). Therefore, it is important to understand if and how their social media use and competence affect their online collaboration with their peers at college.

In this study, we intend to address the following two questions: (1) What is the relationship between social technology competence and digital collaboration? (2) Does the effect of social technology vary by first-generation student status?

To answer these questions, we conduct an empirical study to investigate the association between social media technology competency and digital collaboration of first-generation college students. To do so, we built on the literature in computer supported collaborative learning as well as first-generation students and surveyed a sample of 106 students in a 4-year public urban university. Our regression analysis results suggest that social technology competence is positively related to digital collaboration and such effect is stronger for first-generation students.

This paper is organized as follows. In the next section, we present our theoretical foundation and research hypothesis. Then, we show our research methodology and data collection, followed by analysis of the survey data and discussion of the results. We conclude the paper with limitation of the study and directions for future research.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

To help us understand the impact of SM competence on digital collaboration, we drew upon the research on computer-supported collaborative learning. As Stahl, Koschmann, and Suthers (2006) explained, computer-supported collaborative learning (CSCL) arose in the 1990s as a result of employing software in the learning of isolated individuals. The advancements in the Internet technology in the 1990s and the early 2000s made it possible to connect people in innovative ways and to create an online environment for collaborative work. As students became more competent with the Internet technologies, they started to engage in asynchronous distributed learning groups supported by the computer-mediated world-wide networks. To make CSCL successful, users of the computer networks must have a desire for social interactions and must develop a sense of community of learning (Kreijns, Kirschner, & Jochems, 2003).

In today's society of digital social media, the influence of social media is growing at an unprecedented speed (Lenhart, Purcell, Smith & Zickuhr, 2010). Social media serves many different purposes, such as generating content and sharing photos (Tess, 2013). It also serves as an excellent form of communication when face-to-face meetings are not possible. With the ubiquitous use of social media in education, the purposes of creating, sharing, and communicating can greatly strengthen collaboration among students. Therefore, we hypothesize:

> Hypothesis 1: Social technology competence has a positive effect on perceived digital collaboration.

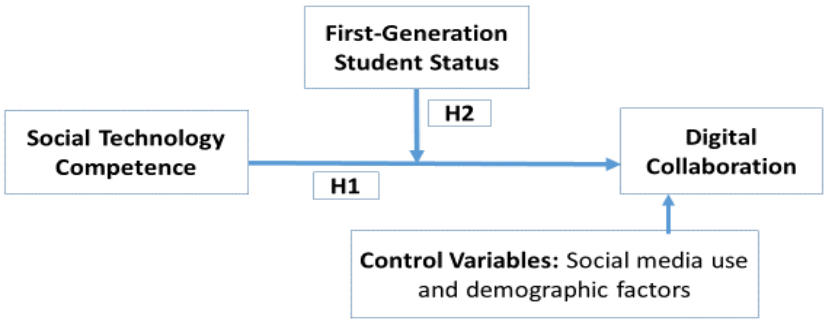
Social media is a great tool for students when searching for educational opportunities and being connected with others. Moreover, it provides a convenient channel for college students to work on collaborative projects and presentations online (e.g., Ellison et al, 2007; 2011). As college students become more competent with the technology, they are more likely to engage in online collaboration.

However, social media technology competence can have a larger influence on a first-generation student's digital collaboration, compared to those who are not first-generation students. This is because students who are first-generation students often encounter more barriers in completing their college degrees than their peers: their lack of financial support from their family and multiple obligations beyond their college responsibilities. According to Nunez & Cuccaro-Alamin (1998), some of the barriers students face include: "poor academic preparation, family responsibilities, and full-time work, for instance, can pose severe challenges to a student's ability to integrate into postsecondary institutional life" (p.2). By conveniently connecting with classmates and instructors through different social media platforms, they may be able to better mobilize the resources in the college classmate network, increasing their collaborative work with their classmates. Therefore, we hypothesize:

> Hypothesis 2: First-generation student status moderates the relationship between social technology competence and digital collaboration.

Both hypothesis 1 and 2 are depicted in the research model in Figure 1 below.

Figure 1: Research Model



METHODS

Research Site and Data Collection

The research site is a four-year public, urban university located in the west region of the United States. It is an ethnically and economically diverse university, as the campus recently reports that 61% of its student population identify themselves as the first in their families to go to college. Data was collected via an online survey in November 2017. The survey asked the students to first identify themselves as "first-generation college students" or not and ensured that no names or personal identity information would be collected to protect respondents' privacy and confidentiality. Then the survey asked students to assess their competence with using various social media tools and to evaluate their collaboration via social media channels. The survey also included questions about their social media usage behavior, such as time spent on social media, frequency of using social media, and the list of social media accounts they have.

A total data sample of 106 participants was analyzed and reported in this article. From a total of 106 students surveyed, 88 students (83 percent) were first-generation students. From this group, 62.26 percent of all students were female and first-generation students. Among all the participants, 72.6 percent were Hispanic or Latino and first-generation students, while 61.3 percent of those students were unemployed and first-generation students. The students who had a family income of less than $25,000 and who were first-generation students accounted for 39.6 percent of all the participants, followed by those who have a family income between $25,000 and $49,999 and who were first-generation students (34%).

The table below summarizes the demographic characteristics of the survey participants.

Table 1: Demographic Characteristics of Participants				
		Non-FirstGen (n=18)	FirstGen (n=88)	Grand Total (n=106)
	Total	17.0%	83.2%	100.00%
Gender	Female	12.26%	62.26%	74.53%
	Male	4.72%	18.87%	23.58%
	Gender Non-Conforming	0.00%	1.89%	1.89%
Ethnicity	American Indian or Alaskan Native	0.0%	0.9%	0.9%
	Asian or Pacific Islander	3.8%	1.9%	5.7%
	Black or African American	3.8%	6.6%	10.4%
	Hispanic or Latino	4.7%	72.6%	77.4%
	White / Caucasian	4.7%	0.9%	5.7%
Employment Status	Employed full-time	0.9%	1.9%	2.8%
	Employed part-time	5.7%	19.8%	25.5%
	Not employed (full-time students Only)	10.4%	61.3%	71.7%
Household Income	1_Less than $25,000	5.7%	39.6%	45.3%
	2_$25,000 - $49,999	2.8%	34.0%	36.8%
	3_$50,000 - $74,999	5.7%	4.7%	10.4%
	4_$75,000 - $99,999	0.0%	1.9%	1.9%
	5_$100,000 or more	2.8%	2.8%	5.7%

All the percentages are based on the grand total of 106 respondents.

Model

Our main model is Equation (1), which is estimated using the ordinary least squares (OLS) model for all students and for the first-generation students only. The model includes the two important measures of social media use, access frequency and duration time. We also control for age, gender, employment status, years of having a Smartphone, and household income.

$$\text{Digital Collaboration} = ß_0 + ß_1\, Competence + ß_2\, Frequency + ß_3\, Duration + ß_4\, Age + ß_5\, Gender + ß_6\, Employment + ß_7\, SmartPhoneYr + ß_8\, Household\_Income + \varepsilon \quad (1)$$

Digital collaboration is measured by two items adopted from Ng (2012); the items were slightly modified to fit the social technology context. Using the 5-likert scale, the two questions are ““*I frequently obtain help with my academic study from my friends over the Internet, e.g., through Facebook, Skype, Blogs.*” and “*Social media technology enables me to collaborate better with my peers on course projects and other learning activities*”. For each dimension, we coded “strongly agree” as 5, “agree” as 4, “neutral” as 3, and “disagree” as well as “strongly disagree” as 2 and 1. As a result, the total rating for each measure ranges from 1 to 5. We took the average of the two items to measure an individual’s overall digital collaboration.

For social media technology competence, we measure it by taking the average of the two items slightly modified from Ng (2012). The two items are: are “*I can learn new social media*

technologies easily" and *"I have the technical skills I need to use social media technologies for learning and to create artifacts (e.g., videos, digital stories, wikis, and blogs*".

RESULTS

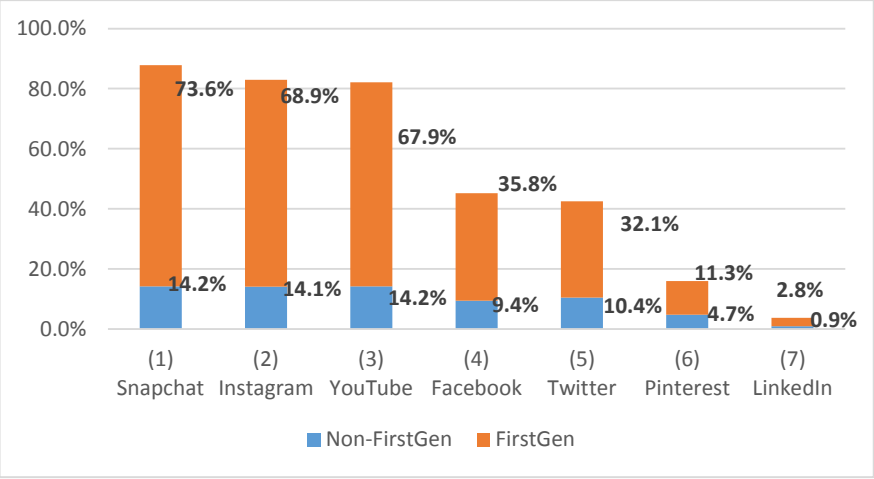
Descriptive Statistics

Distribution of Social Media Accounts by Participants

Among the 106 respondents, 83.02 percent of them own an Instagram, and 68.9 percent own an Instagram and are first-generation students. 82.1 percent of all students own a YouTube, and 67.9 percent of all students own a YouTube and are first-generation students. 45.3% of all students own a Facebook. 35.8 percent of those students own a Facebook and are first-generation students, and 47.2 percent of those students don't own a Facebook and are first-generation students. In total, 87.7 percent of all students own a Snapchat. 73.6 percent of all students own a Snapchat and are first-generation students.

42.5 percent of all students own a Twitter. 32.1 percent of all students own a Twitter and are first-generation students. Only 16.0 percent of all students own a Pinterest. 11.3 percent of all students own a Pinterest and are first-generation students. Finally, 3.8 percent of all students own a LinkedIn. 2.8 percent of all students own a LinkedIn and are first-generation students. The distribution of social media account ownership is represented in the figure below. Please note that percentages in this figure below are based on the grand total of 106 respondents.

Figure 2: Distribution of Social Media Accounts by Participants (n=106)



As shown in the figure, among all these social media accounts, the three most popular types of social media are Snapchat, Instagram and YouTube with 87.7 percent, 83 percent and 82.1 percent respectively. The two least popular types of social media are Pinterest and LinkedIn with 16.0 percent and 3.8 percent respectively.

Social Media Use Patterns among Participants

Among all the first-year college students, the majority use social media every 2-3 hours (33.0 percent), followed by every hour (23.6 percent). For the first-generation students, the pattern is similar with the majority using social media every 2-3 hours (33.0 percent), followed by an equal percent of first-generation students using social media every hour and every 4-6 hours (20.5 percent). The distribution of social media access pattern is summarized in the table below. Please note that percentages in this figure below are based on the column totals.

Table 2: Patterns of Social Media Use by Participants			
	Non-FirstGen (n=18)	FirstGen (n=88)	Grand Total (n=106)
By Social Media Access Frequency			
Frequency1_Every 30 minutes	5.6%	18.2%	16.0%
Frequency2_Every 1 hour	38.9%	20.5%	23.6%
Frequency3_Every 2-3 hours	33.3%	33.0%	33.0%
Frequency4_Every 4-6 hours	22.2%	20.5%	20.8%
Frequency5_Every 7 hours +	0.0%	8.0%	6.6%
Grand Total	100%	100%	100%
By Social Media Use Duration			
Duration1_Less than 1 hour	22.2%	20.5%	20.8%
Duration2_1-2 hours	33.3%	25.0%	26.4%
Duration3_3-4 hours	27.8%	26.1%	26.4%
Duration4_5 hours or more	16.7%	28.4%	26.4%
Grand Total	100%	100%	100%

As shown in the table above, the different amount of time spent on social media by all students in the data sample is equally proportioned between 1-2 hours, 3-4 hours, and 5 hours or more (26.4 percent) and a smaller percent of students using social media for less than 1 hour (20.8 percent). The pattern for first-generation students is slightly different with the largest percent using social media for 5 hours or more (28.4 percent of total first-generation students).

Self-Assessment of Perceived Digital Collaboration

When responding to the two questions on the effects of social media use on digital collaboration, more non-first-generation students hold a neutral stance on the effect of social media on supporting their academic learning, with 50 percent of non-first-generation students as compared to 28.4 percent of first-generation students. However, first-generation students tend to hold more defined views on the subject. The patterns in participants' self-evaluation are shown in the table below.

Table 3: Participants' Self-Assessment of Social Media Use for Digital Collaboration			
	Non-FirstGen (n=18)	FirstGen (n=88)	Grand Total (n=106)
Response to the statement: "I frequently obtain help with my academic study from my friends over the Internet, e.g., through Facebook, Skype, Blogs."			
Agree	33.3%	31.8%	32.1%

Agree strongly	5.6%	14.8%	13.2%
Neutral	50.0%	28.4%	32.1%
Disagree	11.1%	14.8%	14.2%
Disagree strongly	0.0%	10.2%	8.5%
Grand Total	100%	100%	100%
Response to the statement; "Social media technology enables me to collaborate better with my peers on course projects and other learning activities."			
Agree	27.8%	36.4%	34.9%
Agree strongly	22.2%	14.8%	16.0%
Neutral	50.0%	38.6%	40.6%
Disagree	0.0%	8.0%	6.6%
Disagree strongly	0.0%	2.3%	1.9%
Grand Total	100%	100%	100%

Table 3 demonstrates the responses to the second statement: more first-generation students disagree that social media technology enhances collaboration with 10.3 percent disagreeing and none of the non-first-generation students disagreeing.

Spearman Correlations

We have examined the spearman correlations for the variables used in our analysis. For different measures of digital collaboration, as expected, they are highly correlated. Other than that, the highest correlation we observed is 0.36 between digital collaboration and social technology competence, which does not raise any multicollinearity concerns for our regression model. The table below (Table 4) displays the mean and standard errors of variables, and correlations among all the variables.

Table 4: Spearman Correlations

Main Results

Our main results are presented in Table 5, Table 6 and Table 7. Table 5 is based on the first digital collaboration measure, and Table 6 uses the second digital collaboration measure. Table 7 reported the results based on the average of the two measures. Each table presents three sets of results: full sample, first-generation, and non-first-generation.

Table 5 presents the regression results based on the first digital collaboration measure. It shows that in the full data sample, social technology competence is positively related to digital collaboration (0.35, $p < 0.05$). When we look at the findings of the first-generation students, the results are similar to those in the full sample, with a slight decrease of the coefficient of social media duration time (0.34, $p < 0.05$). However, the relationship between social technology competence and digital collaboration for non-first-generation students is not as significant when compared to the full sample and the sample of first-generation students (0.02, $p = 0.96$). Furthermore, although there is a positive relationship between social technology competence and digital collaboration for non-first-generation students, it is much smaller compared to the other sample groups. However, given the small sample size of the non-first-generation group, the results concerning this group need to be interpreted with caution.

Table 5: Main Results based on the First Collaboration Measure

	Full Sample	First-Gen	Non-First-Gen
Intercept	5.07 (3.43)	6.51 (4.38)	5.49 (6.32)

Standard errors are in parenthesis, * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 6 presents the regression results based on the second digital collaboration measure. The results show that, in the full data sample, social technology competence is positively related to digital collaboration (0.28, $p < 0.05$). This is consistent with the result in Table 5 (the first digital collaboration measure). When we look at the findings of the first-generation students, we find that social media duration time remain significant (0.25, $p < 0.10$). However, in the non-first-

generation student group, the coefficient of social technology competence increases but is insignificant (0.51, $p < 0.25$). However, given the small sample size of this group, this result needs to be interpreted with caution.

Table 6: Main Results based on the Second Collaboration Measure

	Full Sample	First-Gen	Non-First-Gen
Intercept	6.72** (2.65)	6.20* (3.3)	12.63* (5.99)
Gender_Male	-0.28 (0.2)	-0.22 (0.23)	-1.07 (0.6)
Age	-0.22 (0.14)	-0.21 (0.18)	-0.58 (0.34)

N	106	88	18
Adj R^2	0.139	0.152	0.077

Standard errors are in parenthesis, * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 7 presents the regression results based on the aggregated measure of digital collaboration. The results show that, in the full data sample, social technology competence is positively related to digital collaboration (0.31, $p < 0.01$). This is consistent with the results in both Table 5 and Table 6. When we look at the findings of the first-generation students, we find that social technology competence remains significant (0.29, $p < 0.05$), similar to the results in Table 5 and Table 6. However, in the non-first-generation student group, the coefficient of social technology competence becomes insignificant, which needs to be interpreted with caution, given the small sample size of this group.

Overall, the main results from the regression analysis supported the first hypothesis on the positive role of social technology competence on digital competence, based on the results of the full sample in Tables 5-7. This positive relationship holds in the sample of first-generation students (column 2, Tables 5-7), but not in the non-first-generation student sample (column 3, Tables 5-7). These results provide evidence to show that first-generation students benefit more from social technology competence in improving their digital collaboration, thus supporting the second hypothesis.

DISCUSSION

The purpose of this research was to investigate the relationship between digital competence and digital collaboration among first-year college students and their peers, mainly at age 18 in their freshman year at college. The findings in our study provided sufficient evidence to show that a higher level of competence with social media technologies has a positive effect on levels of digital collaboration. As shown in the results based on the full sample and first-generation sample in Tables 5-7, the positive effect is consistently significant ($p < 0.05$).

These results are encouraging for first-generation students to develop their digital collaboration with social media technologies and to utilize the technologies to help them accomplish their academic tasks and engage in their college community. In this regard, these results offer important practical implications for higher education institutions to overcome one particular challenge facing first-generation students, which is their disengagement from academic and social experiences, including study groups, interactions with faculty, and extracurricular activities (Engle and Tinto, 2008). As the first-generation college students typically spend the majority of their time working and only take classes part-time, the amount of time that they spend on campus interacting with other students is limited, which inhibits their academic progress (Engle & Tinto, 2008). Having skills to use social media tools, they are more likely to benefit from the communication and information sharing features of social media platforms for online discussing and collaborating with their classmates on course assignments.

In addition, participants provided some examples on how they utilize social media platforms to seek help online from classmates and instructors and to collaborate with their classmates on course projects. These types of social media enabled activities were found beneficial to the college students in our study. This is illustrated in the following quotes:

> *Social media is somewhat helpful, because students can meet up with groups for group projects through social media.*

> *Social media like Snapchat does help social interactions at college because I use it to text people in my class to ask for help or sometimes people post events happening on campus so I know about it too.*

> *Yes, social media is helpful to my academic work. YouTube there are a lot of tutorials that can help with school work. There are a lot of education videos on YouTube. Facebook allows people to network in a click of a button. You can get in contact with clubs, organizations.*

Participants in our study are first-year college students between the ages of 17 and 21, resulting in an average age of 18.06. Our sample of participants is known as the Generation Z, which is the segment of the population born between 1995 and 2010. Growing up in a world of smartphones and free Wi-Fi, young adults of this generation are assumed to be Internet-savvy and proficient in information and communication technology (ICT), especially social networking applications such as Facebook, YouTube, Twitter, Instagram, and LinkedIn (Priestley, 2015). However, our study shows that not all of the Generation Z college students are equally competent at using social media technologies for academic work. Although about half of the participants (51.8%) in our data sample are confident about their technical skills in using social media technologies for learning and to create videos, digital stories, wikis, blogs, 41.5 percent of them take a neutral stance on this. The incoming generation of students has mainly relied on the Internet and technology throughout their entire lives and this has resulted in them becoming learners who rely on technology (Selwyn, 2012). Because of this, social technology use in higher education serves as a way to better engage the students in learning. Therefore, it is worth further studying the relationship between digital collaboration and this type of learning.

Our study contributes to the research on first-generation students by examining the role of social media technology as a useful resource for improving the college success of first-generation students. In addition, this study extends the research on computer-supported collaborative learning from the network of Internet technology to the social media platforms. As a social technology, social media is designed to facilitate human connection and communication. Moreover, our study has suggested that social media enabled the first-generation college students to access resources in the network of their college classmates and instructors, thus providing them with an educational affordance, as suggested by the Affordance Theory (Gibson, 1979).

This study also makes practical contributions to the design and implementation of social technology strategies in higher education. When one's peers are all communicating and interacting on social media, social media platforms will likely become a convenient tool for first-generation students to access and mobilize the resources available from peers in the college

learning environment. This suggests that it is time for higher education institutions to realize the new learning expectations of the new generation Z and consider incorporating social media tools and platforms into the academic program design (e.g., course delivery channel, instructor feedback mechanism) to promote student learning outcomes.

LIMITTATIONS AND FUTURE RESEARCH

We are encouraged by the findings of the research that higher levels of social technology competence would lead to more digital collaborations participated by first-generation college students. However, we need to acknowledge two limitations of the study. First, our findings may be limited by the organizational characteristics of the research site. Because our research site consisted of only one economically-diverse urban public university with a majority of first-generation undergraduate students, the generalizability of the study findings might be limited.. Thus, the findings of this study should be applied to other types of higher education institutions with caution. Second, in addition to the individual competence with social media technology and extent of social media use, other contextual and individual factors may also influence the level of digital collaboration. Future research on contextual factors such as institutional environment would provide potential useful results.

Nevertheless, collaborating with peers through social media is important for college students, especially first-generation college students who lack educational resources at home or in their own community. For the young first-generation students from Generation Z, they expect digital learning tools such as these to be deeply integrated into their education. For them, technology has always been a fully integrated experience into every part of their lives (Kozinsky, 2017). For future research, it would be useful to examine if and how the social technology competence influence college persistence of first-generation students throughout their college years. According to Dennis and colleagues (2005), support from peers, such as sharing notes, studying in groups, and sharing learning strategies, made the biggest impact upon first-generation college students' success in college. For the young generation of college students who are the first of their families to attend college, they should educate themselves on how to navigate social media tools so they can better capitalize on it as an educational resource in the digital learning environment.

"ABSTRACT"

Online reviews of products and/or services have long been recognized as a key driver for consumers' purchase intention. Together with the popularity of the sharing economy platforms, two-way review systems are also widely applied giving both service providers and users a chance to review each other. Psychologists point out that in those systems, people tend to give more positive reviews. Drawn on the heuristic systematic model, this paper focuses on investigating how such positive reviews of themselves form users' perceptions and their influence on the rebooking intention in sharing economy platforms.

KEYWORDS: Two-way review system, Sharing economy, Perceived enjoyment, Perceived helpfulness, Booking habit, rebooking intention

INTRODUCTION

In traditional and electronic commerce, (online) reviews are crucial drivers for business and the focus is always on the consumers and how products/companies are reviewed for the consumers' convenience and choices. Consumer reviews have been found to significantly influence purchase intention (Bae, Lee, Suh, & Suh, 2017; Sparks & Browning, 2011), willingness to buy (Wu & Gaytán, 2013) and to be the critical driver of sales (Ho-Dac, Carson, & Moore, 2013; Maslowska, Malthouse, & Viswanathan, 2017). Review characteristics are normally considered in terms of quality and quantity via the central (systematic) route or peripheral (heuristic) route respectively. While qualitative features of reviews, such as valence, argument strength (K. Z. Zhang, Zhao, Cheung, & Lee, 2014), normally require more efforts to judge, quantitative features, such as volume and rating, take less efforts.

In the new form of sharing economy, where service providers and service users join at a platform, both become the customers to the platform. Since all customers are created equal, peer to peer platforms need to protect both service providers and users equally via the reputation system (Jøsang, Ismail, & Boyd, 2007), or recently called two-way review system. The reputation system, first applied in the eBay, brought both sellers and buyers a chance to review each other after the completion of a transaction (Resnick & Zeckhauser, 2002). The system, however, was not utilized among users and gradually disappeared in 2006. Recently, when sharing economy becomes trendy, two-way review systems are once again introduced and widely utilized. The main purpose of this system is to give both service providers and service users an equal chance to review the provided service and the users' behavior, so that both sides will have more information for their next transaction decisions.

According to psychology, there is an interesting fact that knowing one can review and be reviewed at the end of the transaction, service users tend to behave differently, mostly in better manner while service providers tend to give milder or more positive reviews toward the users. This might generate two things among users, the enjoyment of being nicely reviewed and the perception of

helpfulness for their future bookings, especially when as many as 49% of the times service providers refused to sell their services to certain guests (Fradkin, Grewal, Holtz, & Pearson, 2015). Such enjoyment and helpfulness among the service users who receive positive feedbacks from service providers might potentially keep the users stay with the platform. Among the sharing economy businesses, accommodation tends to have lower competitive compared to transportation, online labor market, etc. (Petropoulos, 2017), thus retention of customers is more crucial to this type of platform.

From the literature review, we identified several research gaps. First, in sharing economy platforms, service providers and users are becoming equal, users can choose which service to buy, providers also have the right to accept or refuse one user. Thus, users care more about their profile quality for higher chance of acceptance by service providers. Previous studies have discussed this, such as how profile pictures influence the rental probability (Fagerstrøm, Pawar, Sigurdsson, Foxall, & Yani-de-Soriano, 2017), however, little research has been done on how reviews from previous hosts help users in their future bookings. Second, previous studies focused on online reviews of products or services and sometimes discussed the emotion embedded in the online reviews (Ullah, Amblee, Kim, & Lee, 2016), however limited research have investigated the impact of reviews about the consumers themselves and their emotions when being reviewed by others (Pettersen, 2017). Finally, shopping habit has been included in studies about online purchases and hotel booking, however, it has not been investigated in sharing economy context.

Within this study, we base on the dual process heuristic systematic model to hypothesize and answer the following research questions: *(1) How do service users perceive when receiving tend-to-be-more-positive reviews from reputable service providers? (2) Will users' aroused perception keep them retaining with the platform? and (3) How will users' booking habit influence their rebooking intention?*

To answer these questions, we conceptualize source reputation as the antecedent for perceived enjoyment via the heuristic route while review positivity influences the perceived helpfulness via the systematic route; perceived enjoyment and helpfulness, under the moderating effects of booking habit will influence users' intention to rebook on the platform. We expect that our research will contribute to the literature of online reviews, especially to new context of reviews of oneself via two-way review systems on sharing economy platforms. The rest of the paper is organized as follows. We first discuss the theoretical background, followed by the hypothesis development. We then use 180 data points collected from a self-reported online survey of Airbnb users to test our research model. Finally, we present our discussion of findings, contributions, limitations and suggestions for future research.

LITERATURE REVIEW

Heuristic Systematic Model (HSM)

This study elaborates on Heuristic Systematic Model – HSM (Chaiken & Eagly, 1989) to investigate the perception and behavior of the service users: how they process the information, bring out the evaluation, and form the decision via two different routes of processing. In systematic information processing, people consider all relevant information such as argument and validity, elaborate and form their judgement; while in heuristic information processing, people base on the information cues (even single cue) that take less efforts to elaborate and form the judgment such as volume and source credibility. When motivation for information processing is high, people tend to go through systematic processing, but they might at the same time go through the heuristic processing (Chatterjee, 2001). Heuristic systematic model has been applied in marketing and IS research to investigate the impact of reviews on purchase intention, system adoption or acceptance, and other intentional outcomes (Luo, Zhang, Burd, & Seazzu, 2013; K. Z. Zhang et al., 2014; K. Z. K. Zhang, Cheung, & Lee, 2014).

Within this study, we argue that, for an Airbnb user, the main effect of the two-way review system that one user considers is how the reviews can help them in their future booking, especially how

the positive content of the reviews would help; while being positively reviewed makes a user enjoyed as a side effect. We therefore conceptualize under the systematic route, the users perceive the helpfulness of the review system based on the consideration of the positive contents of the reviews; under the heuristic route, the reputation of the reviewers increases the enjoyment of the users. These perceptions then influence users' decisions of continuing to use the service.

HYPOTHESIS/MODEL

Source Reputation

Source credibility refers to the trustworthiness of the reviewers that the review readers perceive based on the provided reviewers' information (Li, Huang, Tan, & Wei, 2013) or consumers' perceptions over credibility in terms of the expertise and trustworthiness of the reviewer and review sources (K. Z. Zhang et al., 2014). In this study's context of the two-way review systems, reviewers are the hosts or service providers.

In online websites where consumers' reviews are allowed and displayed, any member can post their reviews, thus which reviewers on which websites to follow is critical to future purchase intention. In sharing economy platforms, instead of reading reviews about the products or services that they might consume, consumers are reading the reviews of their own past service usage written by previous service providers, thus the reviews become sensitive. In accordance with previous studies where the source reputation is decided by the number of reviews, ratings, etc. (Chua & Banerjee, 2015), the service providers' reputation in this case will be the rating, number of reviews they receive, or in simple term, their title of superhosts.

In this study, we argue that when receiving the reviews from previous hosts, the users will have higher perceived enjoyment if the reviews are from reputable hosts or superhosts. Thus, we propose the first hypothesis as follows.

Hypothesis 1: Hosts' reputation has positive influence on guests' perceived enjoyment.

Review Positivity

When discussing the quality of reviews, researchers focused on different dimensions, such as the depth of the reviews or the sidedness of reviews. There has been inconsistent conclusion whether negative reviews or positive reviews are more helpful to consumers. In most studies of the helpfulness of the online reviews, results showed that the more negative words in the review, the more helpful it will become (Baek, Ahn, & Choi, 2012; Sen & Lerman, 2007). Other research found that for products with high average rating, the positive reviews are more helpful and for low average rating products, negative reviews are more helpful (Yin, Mitra, & Zhang, 2016); or the usefulness increases when the reviews have extreme negative or positive contents (Park & Nicolau, 2015). In the context on hotel booking, Sparks and Browning (2011) found that the more positive reviews are more helpful for future booking of the hotel.

In the context of two-way review system, even though the hosts' reviews on guests are written for future hosts, they are reviewing the users themselves. Thus, users are concerned more about the positive contents rather the negative contents of the reviews. And for the sake of smooth future booking, the positive reviews will help to improve the quality of users' profile and increase the chance of acceptance by future hosts. In other words, the higher the positivity of the reviews, the more helpful they are. Based on this argument, we propose the next hypothesis as follows.

Hypothesis 2: Hosts' positive reviews have positive influence on guests' perceived helpfulness.

Perceived Helpfulness

Perceived helpfulness is defined as the extent to which service users perceive the previous service providers' review as being capable of facilitating their future usage of the service (Li et al., 2013). Perceived helpfulness and usefulness are found to have strong effects on intention to continue to use an information system (Bhattacherjee, 2001). In their study of the website socialness influence on intention to use the website, Wakefield, Wakefield, Baker, and Wang

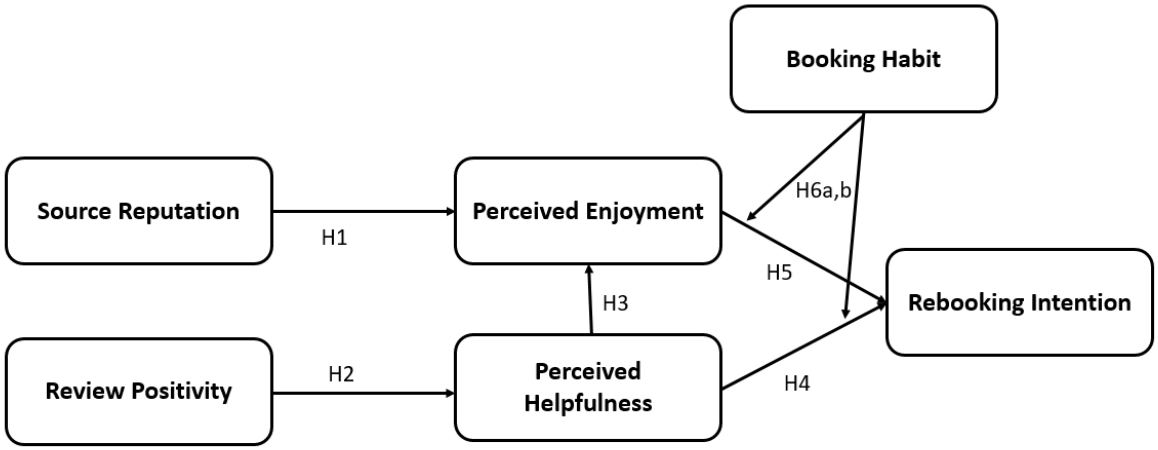
(2011) found that the perceived helpfulness leads to perceived enjoyment among website visitors and both perceived helpfulness and enjoyment then lead to the adoption of the website.
Applying to the Airbnb environment, knowing the positive reviews will increase their profile and their chance of being accepted for the future bookings, the perceived helpfulness will not only make users thrilled and enjoyed, but also strengthens their intention to rebook again. Therefore, we propose hypothesis 3 and 4 as follows.
Hypothesis 3: Guests' perceived helpfulness has positive influence on their perceived enjoyment
Hypothesis 4: Guests' perceived helpfulness has positive influence on their intention to rebook on the platform

Perceived Enjoyment
Perceived enjoyment refers to the extent to which the reviews from the reputation system are perceived to be enjoyable to the service users (Elwalda, Lü, & Ali, 2016). Quite a number of research has found the positive impact of perceived enjoyment on intention to adopt a new system (Dickinger, Arami, & Meyer, 2008) as well as repeating intention such as the repurchase intention (Koufaris, 2002), revisit intention (Reynolds & Ruiz de Maya, 2013), or online service usage intention (Kang, Hong, & Lee, 2009).
In the present study, we assert that when being reviewed by previous hosts, especially positively reviewed, service users will develop an enjoyable perception. Such enjoyment will make service users want to continue to book via the platforms. We then propose the next hypothesis.
Hypothesis 5: Guests' perceived enjoyment has positive influence on their intention to rebook on the platform.

Booking Habit
Habit is defined as "situation-behavior sequences that are or have become automatic… the individual is usually not conscious of these sequences" (Triandis, 1979). According to Chou and Hsu (2016), shopping habit refers to "individuals' general tendency of shopping online irrespective of which website they use for online shopping". Within this study, we define booking habit as the service users' general tendency of booking online irrespective of which platform they use for booking an accommodation.
Shopping habit has been examined in numerous studies both as the antecedent and moderator of purchase and repurchase intention. Khalifa and Liu (2007), in their study on online consumer retention, found that shopping habit has moderating effect on the relationship between satisfaction and online repurchase intention. Chiu, Hsu, Lai, and Chang (2012) examined the impact of trust and shopping habit in online stores found that shopping habit negatively significantly moderates the relationship between trust and repurchase intention. Other research also proposed the moderating effect of shopping habit on the relationships between satisfaction and trust on repurchase intention (Hsu, Chang, & Chuang, 2015).
Within this study, we argue that service users' booking habit moderates the relationship between their perceptions to intention to rebook at the platform. Thus, we propose the last two hypotheses as follows.
Hypothesis 6a: Guests' booking habit moderates the relationship between their perceived enjoyment and rebooking intention.
Hypothesis 6b: Guests' booking habit moderates the relationship between their perceived helpfulness and rebooking intention.

Figure 1 below illustrates our conceptual framework, how review positivity and source reputation influence guests' perceived enjoyment and helpfulness for their future bookings, which in turn will impact the intention to rebook at the platform in the future. Booking habit is proposed to moderate the relationships between perceived enjoyment and perceived helpfulness and rebooking intention.

Figure 1: Conceptual framework



METHODS

In this study, we generated a self-reported online survey questionnaire for data collection. The survey was developed based on literature review including source reputation, review positivity, perceived enjoyment, perceived helpfulness, booking habit, and rebooking intention. Table 1 below gives full details of all the measurements and sources for adaptation. To better capture the Airbnb renters' perception and intention, only users who have booked via this platform before and been reviewed by the previous hosts are eligible to participate in the survey. The survey was then distributed via travelling groups on Facebook to recruit participants and finally 180 valid responses were collected for data analysis.

Table 1. Variable Measurements

Variables	Code	Items	Sources
Review Positivity	PO1	The reviews of me from hosts on Airbnb are very good	(Cheung, Sia, & Kuan, 2012) (Yin, Bond, & Zhang, 2014)
	PO2	The reviews of me from hosts on Airbnb are very favorable	
	PO3	The reviews of me from hosts on Airbnb are very pleasant	
	PO4	The reviews of me from hosts on Airbnb includes positive comments	
Source reputation	*SO1*	*The hosts who reviewed me are reputable*	(Cheung et al., 2012) (Li et al., 2013)
	SO2	*The hosts who reviewed me are highly rated by other guests*	
	SO3	The hosts who reviewed me are good	
	SO4	The hosts who reviewed me are trust worthy	
	SO5	The hosts who reviewed me are reliable	
Perceived enjoyment	PE1	Reading the reviews of me from hosts on Airbnb is enjoyable	(Kang et al., 2009)
	PE2	Reading the reviews on me from hosts on Airbnb is pleasurable	

Table 1. Variable Measurements			
Variables	**Code**	**Items**	**Sources**
	PE3	I have fun reading the reviews of me from hosts on Airbnb	
Perceived helpfulness	PH1	The reviews of me from hosts is very helpful for my future booking on Airbnb	(Yin et al., 2014) (Liao, Tsou, & Shu, 2008)
	PH2	The reviews of me from hosts is very useful for my future booking on Airbnb	
	PH3	The reviews of me from hosts is very informative for my future booking on Airbnb	
	PH4	The reviews of me from hosts on Airbnb increase the quality of my profile	
Booking habit	*HA1*	*Booking at Airbnb is something I do frequently*	(Hsu et al., 2015) (Chiu et al., 2012)
	HA2	Booking at Airbnb is natural to me	
	HA3	Booking at Airbnb is something I do without thinking	
	HA4	Booking at Airbnb has become a routine for me	
	HA5	I have been booking at Airbnb for a long time	
Rebooking intention	IN1	I would like to continue booking at Airbnb	(Hsu et al., 2015) (Chou & Hsu, 2016)
	IN2	I plan to continue booking at Airbnb when I travel in the future	
	IN3	It is likely that I will continue booking at Airbnb in the future	
	IN4	I will consider Airbnb as the first choice to book in the future	

DATA ANALYSIS AND RESULTS

Among 180 respondents, 94 are male (52.2%); most of them are young users in their 20s (114 people, equals to 63.3%) and bachelor or master holders (49.4% and 37.2% respectively). For travel frequency, most people travel from 1 to 6 times per year, accounting for 85.6%. Regarding their Airbnb using habit, more than half of the respondents first booked in Airbnb more than a year ago, why the recency of the last booked varies. Most people book less than 5 times in Airbnb and as a result, receive less than 5 reviews from hosts. Details as in Table 2 below.

Table 2. Demographic Characteristics			
Control Variables	**Category**	**Frequency (N=180)**	**Percentage (%)**
Gender	Male	94	52.2
	Female	86	47.8
Age	Less than 20	2	1.1
	21-30	114	63.3
	31-40	47	26.1
	41-50	13	7.2
	Over 51	4	2.2
Education	High school and below	10	5.6
	Bachelor	89	49.4
	Master	67	37.2
	PhD and above	14	7.8
Monthly Income	Less than USD500.00	34	18.9

Table 2. Demographic Characteristics			
Control Variables	**Category**	**Frequency (N=180)**	**Percentage (%)**
	USD501.00-1,000.00	53	29.4
	USD1,001.00-1,500.00	36	20.0
	USD1,501.00-2,000.00	29	16.1
	More than USD2,001.00	28	15.6
How often do you travel every year?	Less than once	8	4.4
	1-3 times	115	63.9
	4-6 times	39	21.7
	More than 6 times	18	10.0
How long has it been since the FIRST time you booked on Airbnb?	Less than 3 months	26	14.4
	3 to less than 6 months	27	15.0
	6 months to less than 1 year	23	12.8
	More than 1 year	104	57.8
How long has it been since the LAST time you booked on Airbnb?	Less than 3 months	72	40.0
	3 to less than 6 months	54	30.0
	6 months to less than 1 year	28	15.6
	More than 1 year	26	14.4
How many times have you booked on Airbnb?	Less than 5 times	110	61.1
	6-10 times	50	27.8
	11-15 times	15	8.3
	More than 16 times	5	2.8
How many reviews have you received from your previous hosts on Airbnb?	Less than 5 reviews	127	70.6
	6-10 reviews	39	21.7
	11-15 reviews	11	6.1
	More than 16 reviews	3	1.7

In the present study, we applied consistent Partial Least Squares (PLSc) to analyze the data. PLS is a component-based structural equation modeling technique, where PLS is most suitable for model with formative variables and PLSc is more suitable for model with all reflective variables. The data was analyzed in two stages: measurement model, followed by structural model.

Measurement Model

To check the validity of the measurements, we first assessed the factor loadings of each item and the construct convergent validity via Cronbach's Alpha, Composite Reliability (CR) and Average Variance Extracted (AVE). As rules of thumb, Cronbach's Alpha value should be greater than 0.7, CR values greater than 0.7, and AVE values greater than 0.5 (Fornell & Larcker, 1981). After factor analysis, three items including SO1, SO2, and HA1 were deleted because of low factor loadings (smaller than 0.7). The rest of the items were good and included in analysis as shown in Table 3. All Cronbach's Alpha, CR, and AVE values for all constructs well satisfy the requirements, which means the measurements in this study have good convergent validity.

Table 3. Descriptive statistics of constructs				
Variables	**Items**	**Loading**	**Mean**	**S.D**
Source reputation (SO)	SO3	0.872	5.922	1.077

Table 3. Descriptive statistics of constructs				
Variables	**Items**	**Loading**	**Mean**	**S.D**
Cronbach's alpha = 0.894 CR = 0.894 AVE = 0.738	SO4	0.863	5.706	1.250
	SO5	0.842	5.822	1.141
Review Positivity (PO) Cronbach's alpha = 0.943 CR = 0.944 AVE = 0.808	PO1	0.861	5.878	1.177
	PO2	0.929	5.833	1.267
	PO3	0.937	5.906	1.168
	PO4	0.866	6.072	1.197
Perceived enjoyment (PE) Cronbach's alpha = 0.896 CR = 0.897 AVE = 0.745	PE1	0.916	5.561	1.270
	PE2	0.863	5.511	1.302
	PE3	0.806	5.339	1.399
Perceived helpfulness (PH) Cronbach's alpha = 0.909 CR = 0.907 AVE = 0.712	PH1	0.816	5.644	1.315
	PH2	0.836	5.633	1.286
	PH3	0.756	5.461	1.335
	PH4	0.954	5.761	1.412
Booking habit (HA) Cronbach's alpha = 0.895 CR = 0.895 AVE = 0.685	HA2	1.006	4.650	1.641
	HA3	0.754	4.017	1.848
	HA4	0.745	4.011	1.792
	HA5	0.778	4.389	1.771
Rebooking intention (IN) Cronbach's alpha = 0.903 CR = 0.906 AVE = 0.707	IN1	0.769	4.700	1.729
	IN2	0.854	5.689	1.284
	IN3	0.831	5.594	1.324
	IN4	0.903	5.700	1.264

Next, we conducted two tests to confirm the discriminant validity of the constructs, first the confirmatory factor analysis and then the correlations between constructs. Table 4 shows that all items have higher loadings on the constructs that they belong to and Table 5 shows that no two constructs have higher correlation coefficients than the square AVE. These results confirmed the discriminant validity of all constructs.

Structural Model

To test hypotheses and overall model, we conducted consistent bootstrapping with the resampling of 1000. Figure 2 below illustrates the paths' beta values and t-values, and R-square values of dependent variables. Source reputation positively significantly influences the perceived enjoyment among users with beta value of 0.281 and t-value of 4.111. Thus hypothesis 1 is supported. Review positivity also significantly influences the perceived helpfulness with beta value equals to 0.647 and t-value to 10.609, which confirms hypothesis 2. Hypothesis 3 that predicts the impact of perceived helpfulness on perceived enjoyment is also supported with good indicators (beta value equals to 0.544 and t-value to 9.744). However, both perceived enjoyment and perceived helpfulness of users weakly influence their rebooking intention (both t-values are lower than critical level, equal to 0.088 and 1.633 respectively), even though t-value for path between perceived helpfulness and rebooking intention is close to critical level, both hypothesis 4 and 5 are not supported. For the moderating effects, booking habit weakly moderates the relationship between perceived helpfulness and rebooking intention, while significantly moderates the relationship between perceived enjoyment and rebooking intention but in the reverse way. This suggests that when the users have long history of and frequent booking habit on Airbnb, they tend to care less about the reviews and such enjoyment will even less likely to influence their rebooking intention. Thus, hypothesis 6a is supported but not hypothesis 6b.

DISCUSSIONS, CONTRIBUTIONS AND LIMITATIONS

Discussions

This paper tries to investigate the influence of two-way review systems on sharing economy platforms on users' perception and intention to continue to use the platforms. Based on the heuristic systematic model, we hypothesize the heuristic route of source reputation leading to perceived enjoyment and the systematic route of review positivity to perceived helpfulness. The results show that the more reputable the hosts are, the more enjoyable the users perceive when being positively reviewed of the past behavior. On the other hand, the positive reviews are perceived to be helpful to the users for their coming bookings, which is contrary to some of the previous studies where negative reviews were found to be more helpful to readers (Baek et al., 2012). The users are also more enjoyed when they have high helpfulness perception of the reviews they received. However, none of the perceived enjoyment or perceived helpfulness significantly leads to the intention to rebook at the platform in the future. This might be explained that when users read the reviews about themselves from the two-way review system, they might only develop perceptions about the two-way review system, and it will take more factors to bridge to the rebooking intention from there. Finally, to our surprise, users' booking habit has little moderating effect on the relationship between perceived helpfulness and rebooking intention, while significantly weakens the relationship between perceived enjoyment and rebooking intention. This implies that frequent booking users might not be amazed by the positive reviews they got from the system.

Contributions

Theoretically, our findings contribute in several ways. First, this study enriches the literature of online reviews. While most studies focus on the influences of online reviews for products/services that consumers are interested in, limited research have discussed the online reviews about the consumers themselves and their past behavior. Based on the facts that people tend to behave better in places that are not their home and others tend to give more positive comments for

strangers, the findings once again confirm that such psychological inclinations exist and do bring enjoyment and helpfulness to users. Second, the booking habit is once again found to be a significant moderator that leads to rebooking intention. Finally, even though the main purpose of the two-way review system is not to amaze users, it is found to have potential impact on users' intention to continue to use the platform's services.

Practically, it seems both service providers and service users know that the reviews tend to be too positive and there exists the reliability of these reviews in particularly and the trustworthiness of the reputation system in general. Platforms should have diverse measures to build a precise reputation system for the good of both service providers and service users.

Even though perceived enjoyment does not directly influence the rebooking intention among users, but when interacting with users' booking habit, it does influence users' intention. The impact of perceived helpfulness of this reputation system is almost significant, which also implies some potential importance. Platforms should promote this system further as a mean to attract users' retention.

Limitations and Future Research

This study does have some limitations. First, regarding to the theoretical framework development, the heuristic systematic model discusses the influence of aroused judgments on the acceptance of the system. However, in this study, instead of investigating the acceptance of the reputation system, we focus on the rebooking intention, which might be loosely related and the reasons why perceived enjoyment and perceived helpfulness do not significantly lead to rebooking intention. Thus, future research can focus on finding the bridging factors that mediate such relationships.

Second, methodology wise, this study uses self-reported survey to collect data for analysis, which poses several limitations. For example, among all the hosts and reviews that one user received, there should be more reputable hosts and less reputable, and more favorable reviews and less favorable. Therefore, respondents might be confused and do not know which hosts or which reviews to base on for their judgments. Or their responses might not objectively present their behaviors. In future research, other methods should be used to have a comprehensive understanding of the issue; such as experiment can be used to manipulate the source credibility, review valence to explore more of their affects. Text mining techniques and real data exploration on users' behavior might also bring better understanding of the issue.

Finally, there are limitations in the data collection. The sample size in this study is rather small (180 samples) and only focus on Airbnb users. Future research can expand the sample size and test it in other platform users.

CONCLUSIONS

Sharing economy is becoming an important trend and the reputation systems, operationalized as the two-way review systems, help both service providers and users in making decisions. Our study suggests that the positive reviews from reputable service providers strongly enhance users' perceived enjoyment and perceived helpfulness, which while interacting with users' booking habit have potential influence on intention to continue to use the services. Thus, this study contributes to the literature of online reviews of the service users themselves both theoretically and practically.

ABSTRACT

Cryptocurrencies have gained tremendous popularity over the past few years. The purpose of this study is to try to understand the factors that are driving cryptocurrency-related trading activities. Focusing on the well-established cryptocurrency called Bitcoin, we find that online search popularity and the volume of trade in unrelated stock markets positively and negatively, respectively, influence Bitcoin trading volume. We also find no statistical evidence that the underlying sentiment behind relevant financial news influence Bitcoin trading volume. We believe these results might be of great value to investors interested in cryptocurrencies and might instigate further research on this topic.

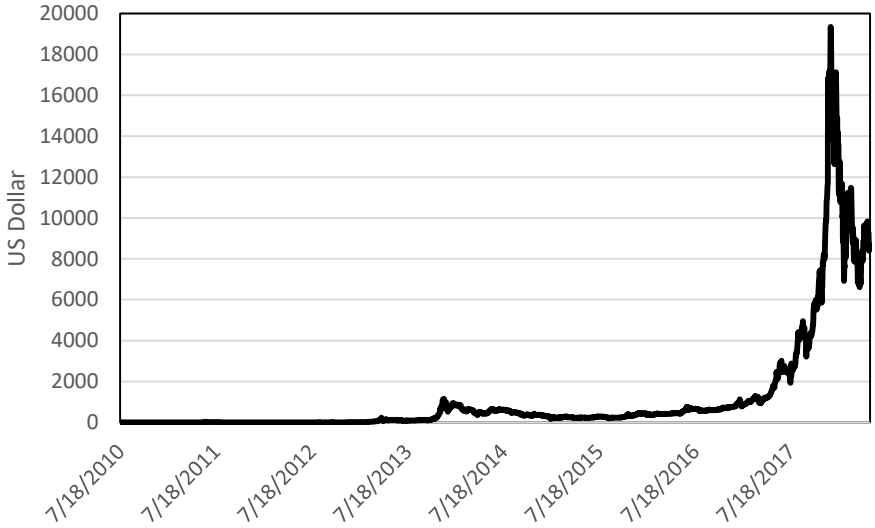
KEYWORDS: Bitcoin, Cryptocurrency, Regression

INTRODUCTION

The year of 2009 saw the birth of a revolutionary concept, namely the online, fully decentralized currency called *Bitcoin* (Nakamoto, 2008). As a payment system, the transactions involving bitcoins are recorded in a public, distributed ledger that requires no intermediaries such as a central bank. That distributed ledger, called *Blockchain*, is heavily dependent on concepts and ideas from the cryptography field, which makes it a member of a new family of information technologies called cryptotechnologies. Due to a similar reason, Bitcoin is now considered a member of a family of currencies called *cryptocurrencies*.

Since its first release, Bitcoin has gained tremendous popularity over the years and exploded in its valuation. For example, Figure 1 shows the value of one Bitcoin in US dollar from July 18th, 2010 to May 15th, 2018. One can immediately see that there was a huge spike in prices in 2017. In particular, Bitcoin price peaked at $ 19,343.04 on December 16th, 2017.

Figure 1. Bitcoin Prices in US Dollar from July 18th, 2010 to May 15th, 2018.



Following the success of Bitcoin, several other cryptocurrencies raised money through initial coin offerings (also known as ICOs) and are now publicly available for trading. As of May 18th, 2018, the website *coinmarketcap.com* listed a total of 1,593 cryptocurrencies having a combined market cap of $369,691,771,684. In all fairness, after the current hype around cryptocurrencies dies down, it is unlikely that all those cryptocurrencies will stand the test of time. The question that arises is then: which cryptocurrencies will survive? Answering this question is crucial for low-risk-tolerance investors and/or investors considering long-term cryptocurrency investment strategies.

One way of determining whether a certain cryptocurrency will stand the test of time is by looking at trading volume. In particular, one can take inexistent or very low trading activities as a proxy for the lack of interest in the underlying cryptocurrency. In this paper, we try to understand some of the factors that might influence trading activities associated with cryptocurrencies. Specifically, we focus on the potential factors that drive Bitcoin trading volume due to the same being currently the most well-established cryptocurrency.

Since cryptocurrencies are online coins, it might be just natural that trading volume is partially driven by the online popularity of a cryptocurrency. Our proxy for online popularity is the frequency with which online searches include the name of a cryptocurrency. As we elaborate on later, we use data from Google Trends to measure search frequency. That said, our first hypothesis is:

Hypothesis #1: *online search frequency positively correlates with Bitcoin trading volume*.

We next hypothesize that other trading activities might influence the volume of cryptocurrency-related trade. For example, one can argue that when a certain market (*e.g.*, a stock market) is attractive, then less resources might be allocated to other trading activities. To test this idea, we measure how the trading volume associated with the stock market index known as the Dow Jones Industrial Average (DJIA) influences Bitcoin trading volume. Our second hypothesis is then:

Hypothesis #2: *the trading volume in non-cryptocurrency financial markets negatively correlates with Bitcoin trading volume*.

Our last hypothesis relates to the influence of financial news on the trading volume concerning cryptocurrencies. It comes as no surprise that financial news heavily influence investors (Barber & Odean, 2007; Fang & Peress, 2009; Engelberg & Parsons, 2011). Recent financial news have mixed feelings when it comes to cryptocurrencies. On the one hand, there are positive news around the acceptance of cryptocurrencies and their valuation gains. On the other hand, there are also several reports on how the anonymity aspect of some cryptocurrencies are making them very suitable to be used for the payments of illegal actives. Since the sentiment behind the underlying news is mixed and, generally speaking, cryptocurrencies are growing in value, we then hypothesize that financial news have no influence on the trading volume of cryptocurrencies. To test this hypothesis, we analyze how the sentiment behind the news published on the Facebook page called *Bitcoin Chart* affects Bitcoin trading volume. Our formal hypothesis is then:

Hypothesis #3: *the sentiment behind cryptocurrency-related news does not significantly affect Bitcoin trading volume*.

In the following section, we explain how we collect the data relevant to the testing of the above hypotheses. This is followed by an explanation of how we analyze the collected data. We finally conclude by elaborating on the implications of the obtained results and how they relate to the relevant literature.

DATA COLLECTION AND PREPARATION

The central variable in our study, henceforth called *Bitcoin_Volume*, measures Bitcoin trading volume. We collected its values from the website *blockchain.info* (Blockchain, 2018). The collected data covers the period of time between July 24th, 2017 and April 19th, 2018, which captures the moment in time when Bitcoin exploded in valuation (see Figure 1 and 2). The resulting 270 observations correspond to the number of daily confirmed Bitcoin transactions. To test Hypothesis 1, 2, and 3, we also collected data from Google Trends, DJIA, and Facebook, as we explain next.

Figure 2. Number of Daily Confirmed Bitcoin Transactions.

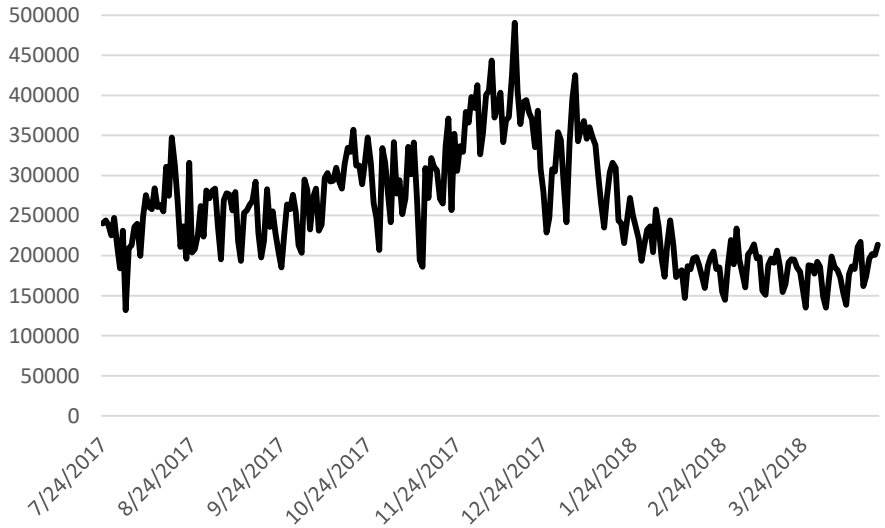


Figure 3. Google Trends Regarding the Term 'Bitcoin'.

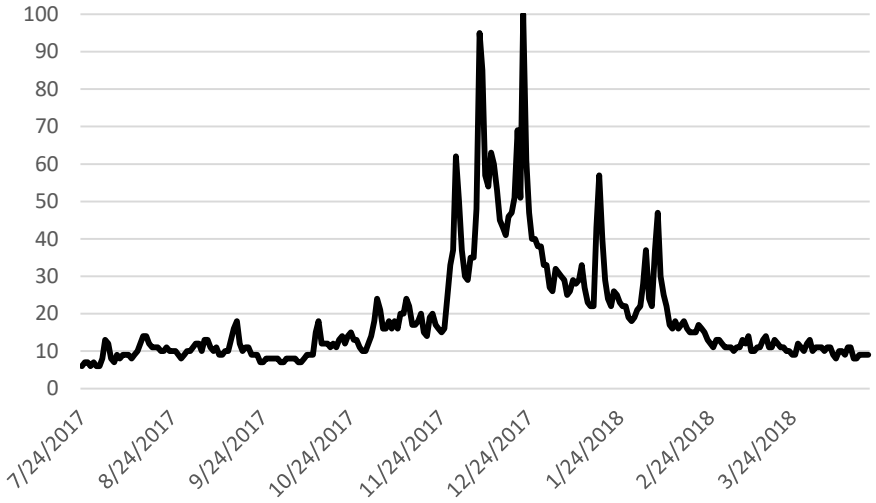


Google Trends

The next source of data is Google Trends (*trends.google.com*). The purpose of the collected variable, henceforth called *Gtrend*, is to determine the online popularity of the term "Bitcoin" over time. Specifically, Google Trends determines the "interest over time" for a specific search term by dividing the number of searches of that term by the total number of all searches done on Google at a given point in time. The resulting numbers are then scaled on a range of 0 to 100 based on the term's proportion to all searches on all topics. In our work, we consider daily searches done by users in the United States of America. That said, we obtained 270 values between 0 and 100 that correspond to how popular the term 'Bitcoin' was during the period of time between July 24th, 2017 and April 19th, 2018. Figure 3 illustrates the obtained data.

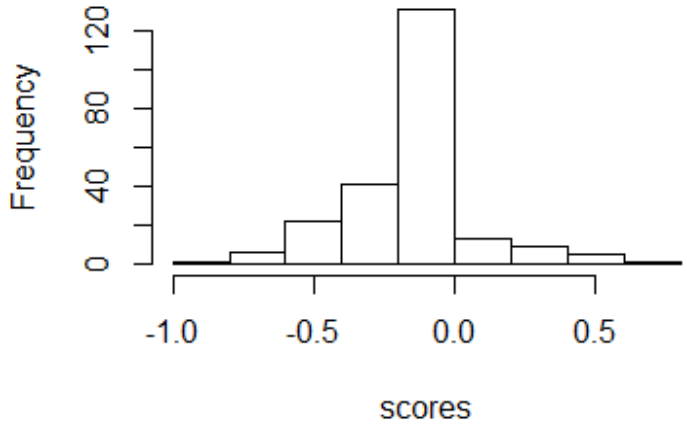
Dow Jones Industrial Average

The next variable we collected, henceforth called *DJIA_Volume*, is about values representing daily trading volumes associated with the Dow Jones Industrial Average (DJIA) index. This data set was collected from Yahoo Finance (Yahoo, 2018). DJIA determines how 30 major American companies have traded on the NASDAQ and NYSE stock markets. Such an index includes very diverse companies, *e.g.*, Apple, Boeing, Caterpillar, Goldman Sachs, IBM, Nike, Walmart, among others. Since the underlying stock markets are officially closed on the weekends, we were only able to collect 187 values during the period of time between July 24th, 2017 and April 19th, 2018.

Facebook

We finally collected financial news related to Bitcoin published on the Facebook public page called *Bitcoin Chart* (Facebook 2018). At the time of writing, that page has the highest number of followers among open Bitcoin pages on Facebook with a total of 402,562 followers. In total, we collected 694 Bitcoin-related snippets across 229 different days between July 24th, 2017 and April 19th, 2018. After collecting the snippets, we estimated the sentiment behind the underlying texts by using a service from the IBM Watson family (Ferrucci *et al.*, 2010; Ferrucci *et al.*, 2013) called Natural Language Understanding. Each resulting sentiment score ranges from -1 to 1 (*i.e.*,

Figure 4. Histogram of the Sentiment Scores Associated with Bitcoin Snippets.



negative sentiment to positive sentiment). Since many snippets were posted on the same day, we averaged the sentiment scores of all snippets published in a day so as to have a single score per day. In our analysis, we denote the resulting variable by *Scores*. Figure 4 plots a histogram of the obtained sentiment scores. One can immediately see that most snippets associated with Bitcoin are either negative or neutral. For the sake of illustration, consider the snippet *"Unpacking five of the biggest cryptocurrency scams to have hit the crypto world.*", which was posted on April 2018th, 2018. The resulting sentiment score of -0.74 returned by IBM Watson is very negative due primarily to the role of the word "scams" in that sentence.

Final Merged Data

We note that the first two collected variables, *Bitcoin_Volume* and *Gtrend*, have a total of 270 values, whereas the last two, namely *DJIA_Volume* and *Scores*, have, respectively, 187 and 229. After grouping all variables by day and removing the incomplete cases, we ended up with a data set containing 160 observations and 4 variables. Table 1 illustrates the final data set, which in turn is used in our analysis described next.

DATA ANALYSIS

After collecting and preprocessing the data, we next analyze the final data set so as to understand how different variables influence Bitcoin trading activities. In our analysis, we start by reporting some descriptive statistics and correlation matrix in, respectively, Table 2 and 3. From Table 2, one can immediately see that sentiment scores are on average negative, as we already mentioned in the previous section, meaning that most of the collected financial news about Bitcoin are negative in nature. Moreover, the minimum (*6*) and maximum (*85*) *Gtrend* values illustrate that some of the original data points we collected before were lost after merging all the data sets and removing missing data. From the variables *Bitcoin_Volume* and *DJIA_Volume*, one can see that the number of daily Bitcoin transactions is rather small when compared to the number of transactions involving stocks in the DJIA index.

Table 1. Sample of the Final Data.

Bitcoin_Volume	*Gtrend*	*DJIA_Volume*	*Scores*
347393	29	341470000	-0.761442
337959	33	346830000	0

Table 2. Descriptive Statistics Concerning the Final Data Set.

Variable	*Mean*	*St. Dev.*	*Min*	*Max*
Bitcoin_Volume	262,529.9	69,505.58	131,875	490,644
Gtrend	18.881	14.234	6	85
DJIA_Volume	370,958,500	106,743,091	118,610,000	823,940,000
Scores	-0.117	0.235	-0.761	0.665

Table 3. Correlation Matrix.

	Bitcoin_Volume	*Gtrend*	*DJIA_Volume*	*Scores*
Bitcoin_Volume	--	0.614***	-0.235**	-0.010
Gtrend	0.614***	--	0.214**	0.025
DJIA_Volume	-0.235**	0.214**	--	-0.026
Scores	-0.010	0.025	-0.026	--
Note: ** = p-value < 0.01; *** = p-value < 0.001				

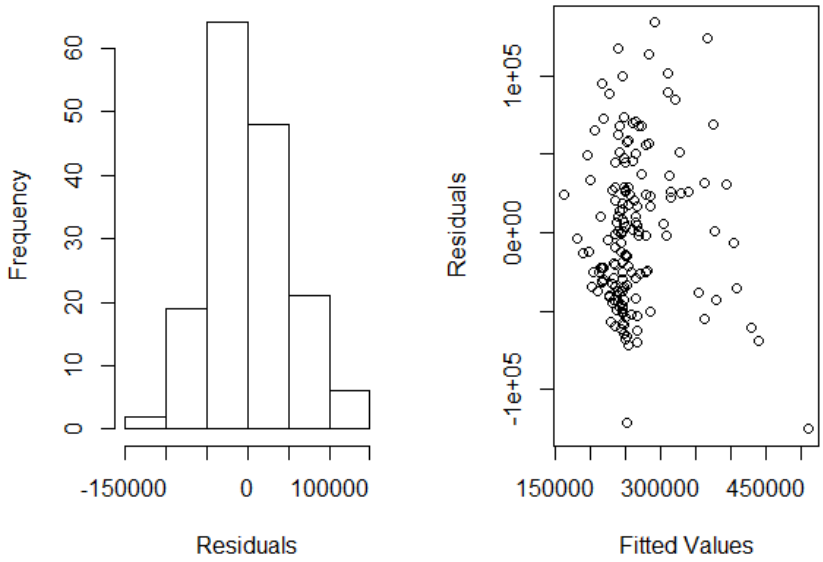
Focusing now on Table 3, one can see that *Gtrend* and *DJIA_Volume* significantly correlates with *Bitcoin_Volume*. While the former is a positive association, the latter is a negative correlation. This indicates that online popularity, as measured by Google Trends, and Bitcoin trading activity tend to move in the same direction, whereas trading activity associated with the DJIA index and Bitcoin trading activity move in opposite directions. Another interesting fact is that the variable *Scores* is not correlated with any other variable. We return to this point later in the paper. Finally, it is noteworthy that *Gtrend* also positively correlates with *DJIA_Volume*. Recall that the variable *Gtrend* measures the popularity of the term 'Bitcoin' over time. That said, we believe that its positive correlation with *DJIA_Volume* might just be spurious since it seems to contradict the facts that the variables *DJIA_Volume* and *Gtrend* are, respectively, negatively and positively correlated with *Bitcoin_Volume*.

We next extend the above univariate and bivariate analyses by developing a multiple linear regression model where *Bitcoin_Volume* is the dependent variable and all the other variables are independent variables. As one can see from Table 3, the independent variables are not highly correlated, which means that a regression model is unlikely to suffer from multicollinearity issues. Table 4 shows a summary of the obtained regression model. The coefficients in Table 4 confirm what we previously suggested. First, holding everything else constant, Bitcoin trading activities are expected to increase when Bitcoin's online popularity (*Gtrend*) increases. Second, when the number of transactions involving stocks in the DJIA index (*DJIA_Volume*) goes up, the number of Bitcoin transactions are expected to go down. Finally, there is no significant relationship between sentiment scores related to Bitcoin news (*Scores*) and Bitcoin trading activities. The R^2 and F-statistic values suggest that our model fits the data well. In particular, it is rather surprising that the three independent variables can explain 51.9% ($R^2 = 0.519$) of the variance in the amount of daily trading activities associated with Bitcoin.

Table 4. Summary of the Multiple Linear Regression Model.

	Coefficient	*Standard Error*	*P-value*
(Intercept)	289909.95	14,245.510	< 0.001
Gtrend	3403.46	277.846	< 0.001
DJIA_Volume	-0.00025	0.000037	< 0.001
Scores	-11132.59	16,445.560	0.499
$R^2 = 0.519$ F-statistic = 55.997 (df = 3, 156; p-value < 0.001)			

Figure 5. Validating the Assumptions behind the Linear Regression Model. (LEFT) Distribution of the Residuals. (RIGHT) Validating Homoscedasticity.



It is important to highlight that we carefully validated the assumptions behind the linear regression model. First, there is strong evidence that the mean of the residuals is equal to zero (one sample t-test; null hypothesis: $\mu = 0$; p-value > 0.999). Second, the distribution of the residuals resembles a normal distribution (see the left part of Figure 5). Finally, the assumption of homoscedasticity seems to hold true (see the right part of Figure 5). Although some observations are flagged as outliers according to traditional guidelines based on Cook's distance, we nonetheless obtained qualitatively the same results when removing those outliers.

DISCUSSION

Cryptocurrencies promise to disrupt many traditional industries and the way humans perceive and handle (virtual) money. Given the abundance of cryptocurrencies currently available to the public, it is just natural that only a limited number of virtual coins will eventually prevail. In this paper, we studied some of the factors that might make some coins more popular than others. Specifically, we took the number of daily transactions as a proxy for popularity. This allows one to understand and potentially predict which coins will stand the test of time. Our initial study was focused on Bitcoin since the same is currently the most popular and well-established cryptocurrency. We then investigated how online popularity, trading volume in an unrelated financial market, and financial news influence Bitcoin trading activity.

Our first hypothesis was that online popularity positively correlates with Bitcoin trading volume. Using Google Trends as a proxy for online popularity, we confirm that our first hypothesis is true. Although it was found before that Google Trends values can partially explain Bitcoin prices (Kristoufek, 2013; Kristoufek, 2015), to the best of our knowledge this is the first paper to establish that online popularity also drives Bitcoin trading volume.

Our second hypothesis was that trading volume in non-cryptocurrency financial markets negatively correlates with Bitcoin trading volume. We used the trading volume regarding stocks in the Dow Jones Industrial Average index as a proxy when testing that hypothesis. Our results

confirm that the second hypothesis is true in that DJIA trading volume negatively correlates with Bitcoin trading volume. To the best of our knowledge, this is the first work to establish such a relationship between non-cryptocurrency financial markets and cryptocurrency trading volume.

Our last hypothesis was that financial news do not significantly affect Bitcoin trading volume. After collecting data from the most popular Bitcoin public page on Facebook and estimating the sentiment behind the underlying posts using IBM Watson, we confirm that the third hypothesis is also true, *i.e.*, there is no significant relationship between sentiment scores and Bitcoin trading volume. It is fair to acknowledge that the lack of relationship might be due to the fact that, despite having hundreds of thousands of followers, the Facebook page we collected data from might not be influential enough and/or the published news might be somehow biased, *e.g.*, too negative. In hindsight, we recognize that it would be valuable to collect Bitcoin-related news from more than one Facebook page and/or other news sources so as to tackle the abovementioned issues.

We conclude this paper by returning to the discussion in the introductory section, namely how can one know which cryptocurrencies will stand the test of time? Our results suggest very practical guidelines to answer this question. First, one can use Google Trends to track the online popularity of a cryptocurrency over time. When this popularity measure starts going down, then our results imply that trading activities involving the cryptocurrency is also expected to go down and, consequently, the public might be losing interest in the cryptocurrency. Second, one can track the trading volume in different non-cryptocurrency financial markets. When these numbers start going down, then it is expected that trading activities involving cryptocurrencies will go up, meaning that the public might be more interested in cryptocurrencies.

Clearly, the above guidelines rely on the assumption that the results we obtained in this paper are valid for all cryptocurrencies, which is unwise to claim without extra data analyses. That said, besides replicating this study for cryptocurrencies other than Bitcoin, we believe it would be of great value to study how generalizable our results are. For example, would one obtain qualitatively the same results when using stock market indexes other than DJIA or different sources of cryptocurrency-related news? Is there any other way of measuring the online popularity of different cryptocurrencies that perhaps complements Google Trends? We argue that answers to the above questions might be of great value to investors considering to trade cryptocurrencies.

ABSTRACT

Little is known about factors affecting adoption of Online Medical Records (OMR). We examined associations of vulnerability perception, usefulness, ease of use, visit frequency and provider encouragement with use of OMR and moderating effects of these variables using National Cancer Institute (NCI) data. Usefulness and provider encouragement played important roles.

KEYWORDS: Electronic Medical Record, Vulnerability, UTAUT, Security, Privacy

INTRODUCTION

Electronic health information provides many advantages. Accessibility and availability of electronic health information beyond providers' offices enhance persons' ability to manage their health and to make informed decisions. In the last few years, availability of electronic health information has expanded significantly (AHA 2016); as such, availability not only provides access to health related data but also facilitates routine tasks regarding health care and helps communicate with providers. According to a report published by The Office of the National Coordinator for Health Information Technology (ONC), about 54% individuals who were offered online medical records (OMR) viewed it at least once in a year (Patel 2018). With rapid increases in availability of electronic health information and Internet use (Pew Research 2018), it is important to understand the factors that facilitate or impede the use of electronic health information by individual patients.

Prior studies on online medical records adoption mainly focused on providers or the organizations; the existing literature has not much discussed patients' medical record adoption. OMR often comprises individuals' clinical records such as medical history, test results, medication information, and health behavior data that may be static and/or interactive in nature (Pagliari et al. 2007). From the patient perspective, OMR have a high potential to improve care if adopted and used by the consumer (Yamin et al., 2011).Tang et al. (2006) concluded that the main reason to adopt OMR by a patient was easy access; credible information and knowledge helped with healthcare and disease management and improved communications with providers. Although beneficial, OMR adoption is often limited to some groups (e.g., racial/ethnic minority and low-income users) (Yamin et al., 2011). Existing studies have discussed the key challenges of OMR adoption by consumers. Liu et al. (2011) discussed various usability challenges of patients' OMR adoption such as functionality, familiarity, and comfort during access of OMR, data accuracy, as well as privacy, security, and trust on the related system. Greenhalgh et al.

(2010) noted ease of use and usefulness as important factors for OMR adoption. In some studies, privacy and security of OMR were shown as major concerns related to OMR adoption. Pagliari et al. (2007) noted that the key challenge of OMR adoption was to find an optimal solution to balance utility and security. The increased frequency of data breaches may have increased concerns about the security of OMR among users. On the other hand, in spite of strong architectural security (such as advanced encryption standards), users often are concerned about unauthorized data access or privacy. While discussing the desirable characteristics of OMR, Mandl et al (2001) specifically mentioned 'confidentiality' as one of the important characteristics along with accessibility, comprehensiveness, and accountability of OMR. Simon et al. (2009) conducted a focus group prior to launching a community-wide electronic health information system in Massachusetts; one of the main concerns for the stakeholders, specifically patients, was about health information privacy and security. This paper aims to find the factors that influence the use of OMR. Using the theoretical framework of the Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh et al. 2003), this research investigates performance expectancy, effort expectancy, social influence, and facilitating conditions as well as the direct and moderating influencing factors. In addition, this study examines an important construct, "vulnerability," which is defined as the privacy and security of the OMR. As discussed above, privacy and security might be key factors for users while using OMR. We utilized data from a nationwide survey conducted by National Cancer Institute (NCI-USA). The contributions of this study include understanding of factors that are important to patients many of who are chronic disease patients, including cancer survivors and generating insight that can be projected to the US population.

LITERATURE REVIEW

Unified Theory of Acceptance and Use of Technology (UTAUT) and Adoption of Online Medical Record

Unified Theory of Acceptance and Use of Technology (Venkatesh et al., 2003) was used as a reference framework. Venkatesh et al.(2003) integrated concepts from several models and theories such as TRA (Theory of Reasoned Action), TAM (Technology Acceptance Model), TPB (Theory of Planned Behavior), MM (Motivational Model) in UTAUT to put forth elements of technology adoption. The four key elements of UTAUT are performance expectancy, effort expectancy, social influence, and facilitating conditions. Performance expectancy is the degree to which the users believe that a system will help to perform a specific task. This definition is similar to Davis et al. (1989) definition of perceived usefulness. This variable was included in our research to capture the users' perspective about the usefulness of the OMR websites/applications. Effort expectancy, as defined by Venkatesh et al. (2003), is the degree to which a system is easy to use to perform a task. This definition is similar to Davis et al. (1989) definition of perceived ease of use and this construct is adapted in our study to understand whether ease of use is helpful for OMR adoption/use. The third major element of UTAUT is social influence, which means someone's believe that the important people he/she knows think he/she should use the system (Venkatesh et al., 2003). This construct is similar to what Ajzen (1991) was mentioned as subjective norm. In this current study, we define provider (including physician and nurse) encouragement as 'social influence' because in health related concerns, physicians probably are the most trusted persons to the patients and physicians' encouragement to adopt OMR may significantly influence the patients. Facilitating conditions in

UTAUT is the organizational infrastructure that the users believe facilitates a specific technology adoption (Venkatesh et al., 2003). As this study examines factors affecting individuals' use, here we adapt this definition that is consistent with the aim. In this study, facilitating condition is defined as frequency of visits by a patient to a provider facility; i.e., our rationale is if the patient visits providers' facility more frequently, it may reflect a higher need on the patient's part and thus the patients may feel more strongly to adopt and use OMR.

Information Vulnerability and Adoption of Online Medical Record

As we discussed earlier, in the context of OMR adoption by patients, privacy and security may play critical role. Even with a sense of urgency, many consumers are reluctant to use online medical records because of privacy and security (Archer et al. 2011; Libert et al. 2015). In prior work, privacy and security was conceptualized in terms of maintaining confidentiality, integrity, availability (CIA) of online medical records such that it can be accessed by authorized users only, protected from unauthorized changes, and retrieved and used by owners/users when they like (Dehling et al. 2014). The major issue relating security and privacy of online medical record usage includes authorized access, relevancy, ownership, infrastructure, and archiving and auditing patients' information. Therefore, Tejero et al. (2012) noted that dependable architecture and reliable implementation policies are required to address these issues; electronic health record systems suffer from lack of protection to sensitive information, data theft, phishing, etc. that may result in higher susceptibility to privacy and security. In this research, we defined technology vulnerability as the consumers concerns about security and privacy with regard to using online medical records. Here privacy is individuals' right to determine whether their personal health related information should be revealed to others as well as to which extent and where the information can be used (Westin et al. 2003). In this research, security is defined as sense of assurance of information safeguard (Anderson 2003). Although there is an ongoing debate on the distinction between privacy and security (Smith et al. 2011), health information privacy is implemented through information security and indeed, the concept of privacy is non-existent without security practices (Lafky et al. 2011). As both security and privacy are important for the protection and appropriate use of health information that resides in online medical records, we considered them as a single construct. Our rationale is that most patients, arguably not tech-savvy, may not consciously distinguish between these two concepts but rather more be concerned about unwarranted events occurring due to any of security breaches or privacy violation.

THEORETICAL DEVELOPMENT/MODEL

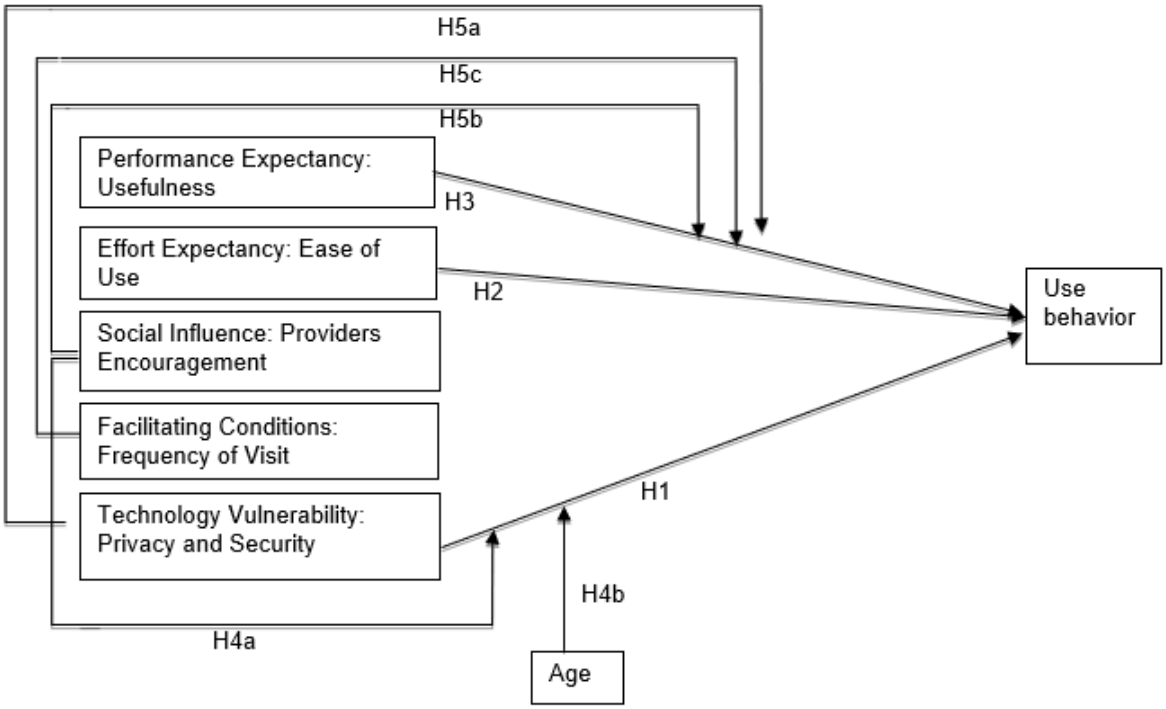

Figure 1: Research Model and Hypothesis

Figure 1 depicts proposed relationships among constructs. Following hypotheses were examined:
H1) Vulnerability is negatively associated with use of health information technology.
H2) Ease of use positively is associated with use of health information technology.
H3) Usefulness is associated positively with use of health information technology.
H4a) The effect of vulnerability on use of health information technology is moderated by physician encouragement.
H4b) The effect of vulnerability on use of health information technology is moderated by age.
H5a) The effect of usefulness on use of health information technology is moderated by perceived vulnerability.
H5b) The effect of usefulness on use of health information technology is moderated by physician encouragement.
H5c) The effect of usefulness on use of health information technology is moderated by frequency of visit.

METHODOLOGY

Data Source

The National Cancer Institute's Health Information National Trends Survey 5 (HINTS 5), Cycle 1 data were used for the study. This survey was conducted between January and April of 2017 and was a single-mode mail survey of noninstitutionalized individuals living in the United States using the Next birthday method. Two-stage sampling design was chosen. First, a stratified sample of addresses was selected from a file of residential addresses and in the second-stage, one adult person was selected from each sampled household. The sampling frame of a database of addresses was provided by Marketing Systems Group (MSG). Responses were obtained from 3,285 subjects, representing 247.8 million US populations.
The focal topic of this Cycle was interoperable (i.e., connected) health care system in the United States and thus, the survey from this cycle deemed suitable for the study objectives in addition to the fact that HINTS data were used in studying Internet search behaviors and technology use (Xiao, 2014 and Heffner and Mull, 2017). Since the focus of the study was to examine those who used the Internet-based health technology, subjects who used the Internet for a variety of reasons, including communication or have a smartphone or tablet were included. In addition, patients who were between 30 and 75 years and had a physician visit in recent years (<2 years) were considered. Such restrictions were thought to improve the validity and relevance of this work. The final study sample had 765 respondents representing 48.7 million US populations.

Measurement of Variables

All variables/measures used in this study came or were constructed from the HINTS 5, Cycle 1 questionnaire.

Dependent variables

The primarily dependent variable used in this study is the extent of online medical record use. In other words, the variable of interest is post-adoption continuance of use and intended to capture actual usage with regards to frequency and/or depth of use (Zheng et al. 2013). Respondents were asked as to how many times they accessed their online medical record in the last 12 months. Response options included: 0, 1-2, 3-5, 6-9, and ≥10 times. Since this study subjects were restricted to adopters, respondents only could select the last four options. Thus, this variable was measured on a 4-point ordinal scale.

Independent variables

Vulnerability: HINTS asked two questions regarding one's concerns and confidence about privacy and safety of online medical records. First, how confident are you that safeguards (including the use of technology) are in place to protect your medical record from being seen by people who aren't permitted to see them? Response options were: 1= very, 2=somewhat, and 3=not confident. Second, if medical information is sent electronically – that is, by computer – from one health care provider to another, how concerned they are that an unauthorized person would see it with a similar 3-point scale. There two items were related and jointly address both

security and privacy issues. Responses on these two items were summated to estimate vulnerability.
Usefulness: this measure came from a single-item question. In general, how useful is your online medical record for monitoring your health? There were 5 options: 5=do not use, 4=not at all, 3=not very, 2= somewhat, 1=very useful. The item was reverse coded for this study. The people choosing 5 were excluded from analysis.
Ease of use: It was measured with a single question. How easy or difficult was it to understand the health information in your online medical record? There were 4 options: 1=very easy, 2= somewhat easy, 3= somewhat difficult, and 4=very difficult.
Provider encouragement: This was a dichotomous scale and measured by asking if health care providers, including doctors, nurses, or office staff ever encouraged one to use an online medical record.

Other variables

The extent literature of technology adoption (Venkatesh et al. 2003) proposed facilitating condition as an important predictor. The extent of online medical use, i.e., facilitating condition, can potentially be directly related to frequency of visits that one made in the recent past. For the frequency effect, a single 6-point Likert scale was used. In the past 12 months, not counting times you went to an emergency room, how many times did you go to a doctor, nurse, or other health professional to get care for yourself? Zero through 4 means the respective numbers of visits and 5=5-9 visits, and 6 meaning ≥10 visits. In addition, demography related variables (age, race/ethnicity, and gender) were used as control variables.

Statistical Analysis

Analyses of survey respondents need to adjust for complex sampling design and nonresponse and noncoverage biases; such an approach is necessary to ensure estimation of correct standard errors needed for valid inference (see HINTS 5 Cycle 1 Methodology Report for calculation of sample weights and replicate weights). Briefly, weights were derived by adjusting for the probability of selecting the household and household nonresponse and finally these initial weights were calibrated to US population counts. Replicate weights were derived using the delete-one jackknife procedure. We provide unweighted descriptions of study subjects and corresponding population-level counts and proportions with use of weights as well. For hypothesis testing, we used simple regressions, main-effects only multiple regressions, and multiple regression with additional interaction effects. For each of these analyses, we accounted for sampling design issues by using weights as advised by the HINTS methodology report.

Table 1: Demography

Variable	N=765	%	Weighted N= 48.7 million	Weighted %
Age			50.9*	0.41**
Gender				
Male	280	36.7	20.7	42.5
Education				
High school or less	100	13.1	9.7	19.9
Some college	218	28.5	15.6	32.1
College graduate or higher	446	58.4	23.3	47.9
Race and ethnicity				
White	523	70.6	32.7	69.1
African American	83	11.2	5.1	10.9
Hispanics	62	8.4	5.0	10.6
Other	73	9.9	4.4	5.9
Occupation				
Employed	473	62.7	32.8	68.3

* Mean in years; ** Standard error
# Cardiovascular diseases: diabetes, heart disorders, hypertension, and chronic or obstructive lung diseases
Weighted estimates account for complex sampling design and project to the US population

Results

Table 1 describes the study subjects. The mean age of them are about 50 years with 36.7% being male. They come from diverse social segments with regards to race (e.g., 70.6% white), education (e.g., 58.4% college degrees), and occupation (e.g., 62.7% employed). Over 52% reported having a chronic disease such as diabetes, heart problems, high blood pressure, and chronic lung diseases. About 50% of these subjects used online medical records 1-2 times. We followed the analytic strategy in Xiao et al. (2014). We ran a simple regression on each of vulnerability, ease of use, and usefulness. We hypothesized that vulnerability is negatively associated with use; the association was not found significant (β= -0.06, P=0.285). However, ease of use (β= -0.2, P=0.005) and usefulness (β= 0.28, P=<0.001), were significantly associated with use of online medical records. In addition, the effects of frequency and physician encouragement were significant (P<0.01) as well.

Next, we ran a series of multiple regressions, which included all of the above variables as well as control variables and results were presented in Table 2. The results from the main-effects model did not show association (β= 0.03, P=0.63) between vulnerability and use; however, ease of use became marginally significant (β= -0.16, P=0.072) while usefulness remained strongly significant (β= 0.26, P=0.001). Thus, H2 and H3 were supported while H1 was not.
Next, we examined the interaction effects of vulnerability and usefulness separately in two models. None of interaction effects of vulnerability with age (β= -0.00, P=0.619) and provider encouragement (β= -0.13, P=0.236) were significant. While interaction between usefulness and vulnerability was not significant (P=0.658), that with provider encouragement (β= 0.37, P=0.001) and frequency (β= 0.07, P=0.035) were. Thus, H4a, H4b, and H5a were not supported and H5b and H5c were supported.

DISCUSSIONS

This study investigated factors that affect online medical records use among adopters. A nationally representative sample was used to examine the hypotheses. To the best our knowledge, this is the first study to investigate online medical records use among a nationally-representative pool of subjects, many of who have been suffering from chronic diseases; indeed some (15%) of these patients also suffer from multiple chronic diseases. A number of our hypotheses have been supported. In particular, usefulness was found to have a strong and persistent effect on online medical records use after controlling for frequency of provider visits and other variables. However, surprisingly we did not find the effect of vulnerability concerns on use. Several potential reasons can be speculated. These subjects already adopted the system and thus, they might have thought over and worked out on such concerns before actually starting to use online records. It is also possible that an implicit trust dynamics was at play since they made a decision to use online records. The empirical evidence of physician encouragement on online medical records use further supports such a plausible reason. That is, patients might have derived trust implicitly since their providers encouraged them to use the system or having seen their providers use the system themselves as many physician practices in the US started using health IT such as EPIC. Furthermore, there was lack of information on system designs (e.g., login features). It would be reasonable to assume that there were heterogeneity and that might have led to confounding of the vulnerability effect. Alternatively, the effect of vulnerability is less predominant among adopters and unfolding such an effect requires much larger sample size that that was available for this study.

Table 2: Linear Regression of Online Medical Records Use

Parameter	Main effects model		Interaction model[1]		Interaction model[2]	
	Estimate (SE)	P-value	Estimate (SE)	P-value	Estimate (SE)	P-value

The extant research on technology adoption demonstrates consistently the effect of ease of use on adoption. This study found an interesting pattern of effects of ease of use on online medical records use. In particular, while ease of use appeared strongly related to use in the simple regression model such an association became noticeably weaker or disappeared in the multivariable analyses. Ease of use may be confined to some segments of patients; thus, once those effects (e.g., demography, visit frequency, etc.) are accounted for, the impact of ease of use decreases. It is also possible that experiential learning mitigates ease of use.

Implications for Theory

There has been extensive research on technology adoption and less so on drivers of continuous use of technology. Our work focused on the later and directly extends the literature. In particular, while past studies have predominantly focused on ecommerce our work extends to health care. With a growing older population and segment suffering from chronic diseases early on their life, such a work is considered timely and beneficial to society. In light of our findings demonstrating effects of usefulness and, to some extent, ease of use, this study holds promise of an integrative theory of adoption and continued use.
Subjective norm has played a key role in the theory of planned behavior (TPB). Researchers have also used TPB in the context of e-commerce. In our study we found a consistent and strong effect of provider encouragement. A close construct is social influence as is conceptualized with the framework of UTAUT. While provider encouragement is not subjective norm in the sense subjective norm has been operationalized in the e-commerce literature or social influence, our operatonalization of social influence as provider encouragement is close to normative influence in that provider encouragement provides assurance and probably conveys expectations implicitly. This study provides grounds for extending or re-conceptualizing normative social influence when researchers need to investigate health IT use.

Implications for Practice

Chronic conditions-especially, multiple chronic conditions-impacting people's life are on the rise and they are affecting early on (Butorff, Ruder, and Bauman, 2017). OMRs create a patient-centric platform with the potential ability to support patient-provider information sharing and collaboration, improve health care outcomes and reduce costs at the individual and system levels. From the health care systems or policy makers' perspective, this study provides an understanding of how patients can possibly be persuaded to use OMRs. For example, consistent effects of provider encouragement imply that physician or nurses can be a strong stakeholder helping patients adopt and use OMRs and they should discuss with their patients or enquire about this when an opportunity arises.
This study has implications for developers and vendors of OMRs. Among many drivers of use of OMRs, usefulness was investigated extensively. Usefulness was found to drive use alone and in conjunction with other variables. This also found that there are attributes of OMRs that drive the perception of usefulness. Thus, developers or vendors should attempt to enhance these features and engage with patients to help understand patients' needs and expectations.
Although not predominant, but there remain some concerns for ease of use at least for some patients. These patents may belong to some demographic strata. For example, race and gender showed some effects on use of OMRs. It is possible that needs and expectations are different in these patients. An adequate understanding of these issues will help develop features and messages targeted to these patients that will increase the likelihood of further use.

Limitations and Future Research

The study findings should be interpreted with caution because of a few limitations. First, unlike standard measures used in studying constructs affecting technology adoption such as usefulness, ease of use, HINTS data provide a single item measures for ease of use and usefulness. While a single-item measure may be unambiguous, if properly designed, a validated multi-item measures tend to generally better capture a construct. As some were used in previous waves (e.g., online records use), it may be speculated that measures have been subject of methodological rigors undertaken by the sponsor. In addition, prior research investigated post-adoption technology use with single-item measures (Zheng, Zhao, Stylianou, 2013). Future research should address the issues related to measures. Second, because data came from a cross-sectional study design, it precludes the causality between independent and dependent variables. Third, respondents' personalities, attitudes or skills may affect online records use. For example, a person with confidence in his or her ability to manage health technology may utilize online records more frequently. Fourth, there is limited information on the design feature of online medical records. Thus, system design issues or characteristics embedded in security and/or privacy concerns and their relationships with continued use of online records are not fully understood and left for future research. Finally, the impact of online records use on patients' health care outcomes should be examined in the future.

CONCLUSION

A national survey on health technology adoption provides insightful information on healthcare consumers' use of online medical records. Predominantly, usefulness drives the extent of use, which is also strongly affected by a need reflecting factor, frequency of visits. In addition, the effects of usefulness, are moderated by frequency and provider encouragement. Developers and vendors should work with patients and their healthcare providers to reinforce usefulness perceptions.

ABSTRACT

Third world countries remain an unexplored market. Those markets can be as profitable as those of Europe and America if few barriers can be overcome. The main purpose of this study is to show how companies can use big data and its analysis tools successfully for business in developing countries. Businesses could achieve competitive advantage by gathering data from those countries, analyzing and using them to improve decision making. Moreover, big data tools can generate reliable measures to increase profitability in an environment that does not always depend on technology in ordinary business transactions.

KEYWORDS: Big data, IT tools, Third world markets, Technology, competitive advantage, Digital divide, Information Technology, Developing nations, Developing countries, Third world countries, Development

INTRODUCTION

Compared to the rest of the world, third world countries use technology less in business transactions even though people in those areas are catching up with other nations in daily use of technology for other life aspects. The marginal used of technology in business transaction can be attributed to the high cost of technology. As a result many third world countries cannot afford the technology necessary to efficiently run a business; even though some businesses in those areas could compete on the global market with technology. Moreover, companies looking to expand their market share may see the need to venture into third world areas. With the current globalization, expanding to third world countries might be a necessary leap that most companies will need to remain competitive.

However, since third world countries are not well known to incoming businesses, there should be a thorough analysis and understanding of the population needs, the environmental restrictions and the market limitations. Finding data on these markets may be a big challenge for businesses willing to analyze and improve their chance of success in those markets. The challenge will be to find data to analyze for these markets. The next step will be using the various big data tools to analyze those data. To accomplish these tasks the current paper focuses on how technology can help in getting and analyzing big data for developing countries; and therefore, increase a change of success. It is important to review existing literature to understand the technology available in third world areas, as well as the analysis tools.

LITERATURE REVIEW

The use of technology and its applications has significantly increased around the world in the recent years. This increase can be attributed to the fact that, information technology, especially mobile technology has become affordable even for people in third world countries. Analyzing the technologies available in different parts of world can help understand how business can used technology to grow and conquer new markets.

Importance of Technologies in Third World Countries

The use of the technology may not give businesses significant advantage in developed countries; however some third world countries having access to technology can make a big difference. The availability of technology can help businesses find or create new or better opportunities. Technology can help businesses and governments offer services otherwise not possible without technology (Heeks & Stanforth, 2015). Businesses may use technology to improve efficiency and effectiveness. Third world countries are clearly at a disadvantage when it comes to technology, but businesses in those areas can still see its benefits (Jimba, 1999). Governments are relying more and more on new technology and applications to resolve various problems and issues faced by third world countries (Heeks & Stanforth, 2015). Currently, by the means of online connectivity through mobile technology such as smart phone, laptops as well as social media application, businesses can reach customers in remote areas.

The recent progression of technology in developing countries has seen the growth of social media and the internet which allowed businesses to reach their customers (Jimba, 1999). Companies in developing countries are gradually beginning to advertise their products and services online. The progress of online shopping has increased the technology requirements for businesses. Those businesses are now able to communicate with their customers and better understand their needs and preferences; which has not always been the case in third world countries (Jimba, 1999). Without technology, businesses and governments in developing countries faced obstacles and difficulties in communicating with people and collecting information about their preferences and opinions. Moreover, with the help of technology, those businesses could collect and share data and information with each other as well as with the government. The collection of data can successfully be achieved today with the availability of large data storage, advanced technology tools and applications (Gonzalez-Brambila, et al., 2016). However, those countries are still at a disadvantage when it comes to technology compared to developed areas.

Limitations of Technology in Developing Countries

In developing countries it is very difficult for businesses to fully take advantage of technology as businesses do in developed countries. In third world countries, businesses are confronted with a variety of obstacles (Heeks & Stanforth, 2015). Those obstacles include but are not limited to: poverty, illiteracy, capital requirements and technology transfer. As a result, many businesses suffer from low returns, which lead to high rates of bankruptcy (Gonzalez-Brambila, et al., 2016).

Poverty: Countries are characterized as third world mainly because of the high level of poverty. Poverty is the primary reason most third world countries' government, businesses and citizens are behind in technology usage. Gonzalez-Brambila, et al. (2016) reports that the requirement associated with the latest technologies may rise higher for third world countries because of the high cost to adapt to the low technological environment. The cost of the required powerful

equipment need for some technology can grow higher than many countries can afford. In addition adapting new technology to poor infrastructures may prove more costly than the total cost of the same technology in rich countries because of the capital required.

Capital Requirements: By comparison to developed nations, many third world countries lack the basic equipment required to successfully install and use most technologies. Those requirements include among other things, electricity, internet connectivity, computer equipment. As a result, companies or individuals attempting to invest in new technology may be face with a high price tag not only of the technology cost, but also the necessary equipment to make the new technology functional. Heeks & Stanforth (2015) argue that the cost can rise so high that it most businesses cannot afford it. The cost can also rise since developing countries have to import all the required technology from developed nations (Shahidullah, 1999); because almost nothing is manufactured locally.

Technology Transfer: Technology used in third world countries are for most created for developed countries, those technologies may sometime be too advanced and not adapted. It costs more to customize the transferred information technology to suit business in developing areas because the way businesses are conducted in third world countries is very different from that of developed countries. To be successful, technology destined for third world nations should take into account among other things the customs, the location, the language, the existing technology, the government rules and regulations, the method of payment, the population skills. The market for products and services in developed areas is very competitive especially with the advanced in information technology compared to third world countries which have limitation as far as technology is concerned. With the need to increase their market shares most companies are compelled to establish a global presence and explored new markets. Those new markets are for most in developing nations especially with the growing needs of the population triggered by the internet and social media and other information technologies. Global connectivity is creating a lifestyle change in developing countries to mimic that of people in developed nations.

Targeting the third world countries create a big opportunity for companies around the world to sell their products and services. However, success in those areas will be determined by the ability to collect and analyze data and provide useful information for business to incorporated in their decision making. Businesses are acquiring big data analysis tools to understand the need of those areas and strengthen their position in those markets. Many tools with the capability of organizing and grouping the data can be used to help companies gain competitive advantage (Anonymous, 2017).

Characteristics of Big Data

Vast amounts of data are collected daily around the world whether intentionally or not. Those data come from multiple sources including browsing histories, bookmarked websites, GPS histories, shared data in social media, web searches and more (Anonymous, 2017). By their simple nature, those data can be classified into different categories (Kuner et al., 2012). They can be structure and organized in table and other prearranged form, or unstructured and needing to be well-arranged before use (Nunan, & Di Domenico, 2017). Combining all these complex data is what is simply called Big Data. Kuner, et al. (2012) defines Big Data as huge volumes of data that can't be analyzed using normal analysis tools intended for small data; since the tools designed to convert big and complex data into understandable pattern were not available (Nunan & Di Domenico, 2017). Conventionally, data with similarities were grouped in

categories very convenient for analyses. They consist of all the data available around the world that can be transformed in a useful format and analyzed by businesses to make informed decisions and gain competitive advantage. The very nature of Big Data makes such grouping nearly impossible. Some data are difficult to collect, save, process, and analyze because of their massive volume (Jain, 2016). To effectively engage in big data analyses, it is important to first understand its massiveness and complexity. The complexity of Big Data can be divided into three basic sets known as the 3Vs: volume, variety, and velocity (Lee, 2017).

Volume: Jacobson (2013) claims that, about 2.5 quintillion bytes of data are created every day. The volume of big data can be characterized as large amount of data generated at a very fast pace (Lee, 2017); which made it challenging to process due to its massive size. For instance, the cost associated with big data would have been very high because data storages used to be very expensive (Sivarajah, et al., 2017). Luckily, today progresses in technology, lead to the creation of affordable data storage which alleviate the cost of collecting and storing large volume of data and therefore making big data analysis possible.

Variety: Big data consist of multiple types of data. Sivarajah, et al. (2017) state that big data includes pictures, texts, videos, graphics, charts, tables and much more. Those data can be structured and/or unstructured according to Nunan & Di Domenico (2017). The structured parts of the data are organized in database table and can easily be analyzed using the traditional data analysis tools. The unstructured portion of the data on the other hand, can be hard to categorize because of their unconventional nature; they may include texts, photos, videos, social media, audio, etc.

Velocity: velocity refers to how fast data is being generated and processed. Jacobson (2013) reports that, almost 90% of data available today, have been generated in the last few years. It used to be easy to process and analyze data because it was generated at a slow rate (Sivarajah, et al., 2017). Today however, data is being generated so fast that, as to necessitates high capacity analysis tools to keep up with the fast pace, which as some may characterize it, almost in real time. Big Data include any type of data that can be analyzed to return benefits.

Benefits of Big Data

Businesses invest in Big Data for different reasons. New businesses want to know the ideal location to establish the new company, what customers like, and how to gain competitive advantage. Existing businesses need to identify new products or venues that can be profitable; to enhance the business processes and to understand the market environment. Big Data may help companies attain their desired outcomes (Kuner, et al., 2012). The sought after outcomes may include among other things: reducing costs of operations, making better decisions, and providing customers with better products and services. Big Data can help businesses achieve efficiency and effectiveness in their operations by predicting the right demand of products and services (Lee, 2017). This ability to predict come develops by keeping close communications with the customers as well as collecting data from various sources to help learn about customers' needs and preferences, the prices they are willing to pay. Gandomi and Haider (2015) suggest that Big Data can help businesses identify the necessary medications for their processes to remain competitive in the market place. Therefore, Big Data tools might be beneficial and help forecast the future trends in the market.

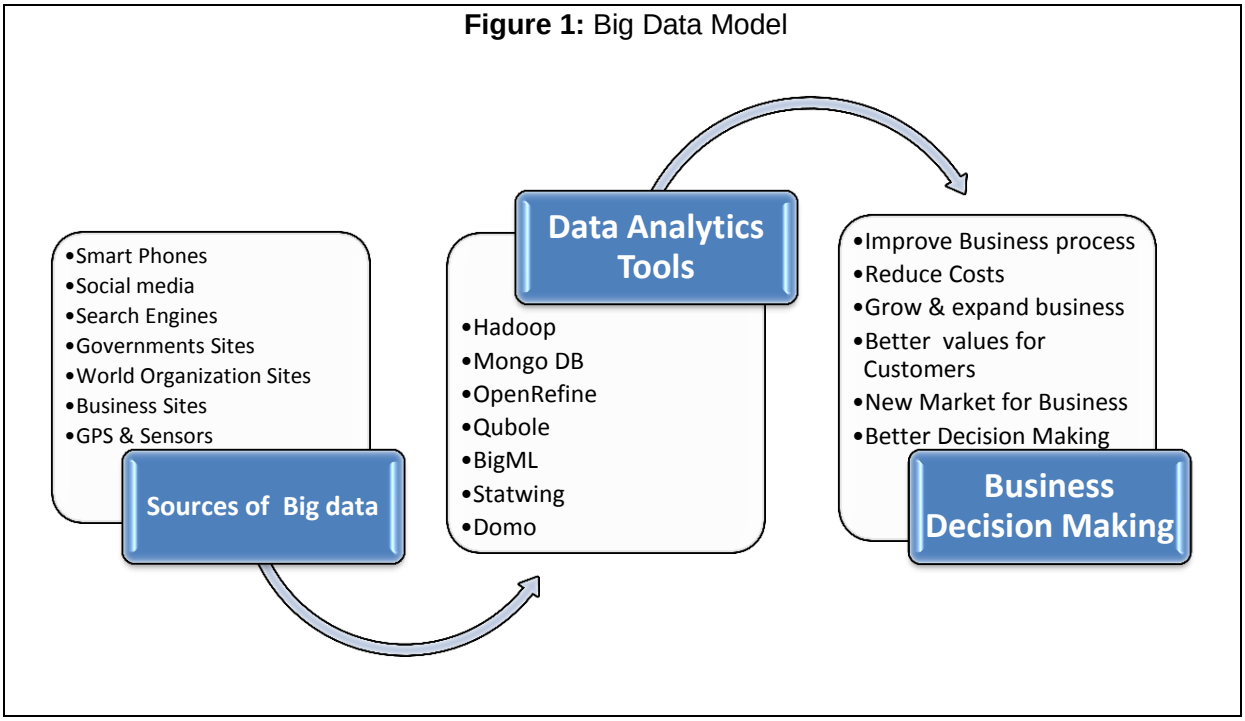
RESEARCH METHODOLOGY

The literature suggests that, in third world countries, big data and its tools can help local business trying to maximize their profits and international companies looking to invest in new markets. This study proposes a model showing how businesses can use big data analysis tools to secure their position on today global market.

Model

The model in this study shows how businesses can use Big Data and its analysis tools to gain competitive advantage in developing nations and maximize their profits in today's global market. First, data should be collected data from the many sources forming Big Data. Then the data will be analyzed using the appropriate big data analytics tools. Finally companies can use the result of their analysis for decisions making.

Figure 1: Big Data Model



Sources:

Today, data is continuously being collected from different sources on almost every aspect of our environment, our society and our life. All those data sources contribute to Big Data. The data sources include but are not limited to social media, public and private websites, google, smart phones apps, Government publications and committees, GPS, and sensors.

(1) Government Agencies: accurate and reliable information are found on government websites (Marr, 2015); including information about the people, culture, crimes, markets and industry.

(2) International Organizations: is a great source for information about countries history, education, markets, economy and much more (Marr, 2015).

(3) Public Websites: provide information about the news, weather, currency, and more; which, can indirectly affect businesses.

(4) Company Website: can notify companies about customers visiting their website, the number of views of specific products, the number of visitors and feedback from customers.

(5) Social Media: It is a great place for businesses to collect data, communicate with customers and learn about them. It includes Facebook, Twitter, LinkedIn, Skype, YouTube, Pinterest…

(6) Smart Phones Applications: when customers sign up for Apps, companies can collect data such as their names, age, location, preferences, emails, etc...

(7) GPS: By using the GPS, in driving, flying, navigating or walking, generate data that can be essential for business decisions.

(8) Sensors: sensors are use almost everywhere and can generate a huge amount of real-time data as their technologies have improved tremendously.

(9) Search Engine: including Google can be considered as one of the biggest sources of information. Individuals and businesses can use them to know about many things.

Tools:

After data gathering comes the analysis phase which required big data analysis tools used for simplifying and making data understandable. Those tools include: Hadoop, MongoDB, OpenRefine, Qubole, BigML, Statwing, and Domo.

(a) Apache Hadoop: open source software used to store and organize large amounts of data.

(b) MongoDB: big databases that can handle frequently changing big data. It is reliable for real-time data.

(c) OpenRefine: open source software that organizes chaotic data in big data for effective use.

(d) Qubole: tool that uses data platforms based on clouds technology to process big data.

(e) BigML: tool that uses machine learning to simplify the big data gathered from multiple sources and generate useful models for decision making.

(f) Statwing: tools that organize the big data in a way that can easily be manipulated to generate new information.

(g) Domo: tool that saves, processes, and converts companies' databases, into charts and other visualization outputs.

Research Design

Some data sources such as GPS, sensors, and some Government publications are limited only to develop nations. Most third world countries have unreliable GPS and maps due to the poor quality of infrastructures. Table 1 presents the availability of the sources to businesses in the Third World Countries and the Developed Countries where (Y: Available, N: Unavailable).

Table. 1: Availability of Sources

Sources		Google	GPS	Sensors	Smart Phones	Websites	Social Media	Government
	Developed Countries	Y	Y	Y	Y	Y	Y	Y
	Third World Countries	Y	N	N	Y	Y	Y	Y

Regardless of the size of the company, most data sources are available online and are excellent places to get input for the big data analysis tools (Marr, 2015). Data from different sources are fed to big data tools which will organize them and process them into information. Moreover, data analytics tools enable businesses to present the information into visualizations forms including charts, tables, graphs and much more. As a result, businesses have access to information they can use in decision making. Companies can use these outcomes from big data analysis as a powerful tool to succeed in business in third world countries. These analyses can help companies understand third world the market and the need of potential customers. Firms in developed countries can take decisions based on real time information available in the big data to gain competitive advantage in the global market.

On the other hand, businesses from the third world countries may also benefit from the analyses and improve their processes, products, prices, and communications with current and potential customers. Third word areas businesses can also compete to a certain degree on the global market and attract customers around the world. However high capitals investment required may be overwhelming for businesses in the third world countries. In any case business in third world markets lack advanced technologies which may limit their access to big data and its analysis tool. Therefore, big data and its tools will mostly benefit businesses in developed nations. Businesses in developed nations, especially the big ones, will incur lower costs than in using big data and its tools that any business in third world nation. This advantage is due to the fact that in most developed nations, large companies have already been using big data and its tools to compete nationally as well as in some international markets.

SUMMARY AND CONCLUSION

To be competitive in today's global market, businesses can adopt information technology as an integral part for their process. The current paper suggests that big data and its analysis tools could help businesses compete in third world countries. With globalization, businesses in third world countries could overcome the limitations due to the lack of advanced technology that can secure competitiveness and maximize profits. Although big data tools are expensive for third world nations, they can be very beneficial and rewarding for the businesses. In the long-run, the benefits of investing in big data and it technology will outweigh the costs; and businesses in both developed countries and third world countries can enjoy the benefits. The next step in this research will be to analyze the different big data tools and determine the most appropriate for different regions.

ABSTRACT

There is an increasing trend to use cloud for data storage and applications. However, the security and privacy issues in the cloud environment become the major concerns for cloud users and organizations. Masquerade attack is one of the most critical attacks in the cloud. To exploit the sequential feature of the masquerade attack dataset, we propose to use Recurrent Neural Network (RNN) with Long Short-Term Memory (LSTM) to detect masquerade attacks. We also applied word vector to preprocess the dataset to provide more exploitable information for prediction. Experimental results showed that the proposed RNN methods obtained better performance than the traditional multilayer perceptron methods. Moreover, the RNN with word vector method showed promising performance in identifying both the normal and masquerade records.

KEYWORDS: Recurrent neural network, Cloud computing, Masquerade detection, Multilayer perceptron

INTRODUCTION

Research in cloud computing has been receiving a lot of attention from both academic and industrial worlds. According to Amazon (Amazon, 2017), “Cloud computing is the on-demand delivery of compute power, database storage, applications, and other IT resources through a cloud services platform via the internet with pay-as-you-go pricing.” However, the security and privacy issues concerning the storage of data in the cloud have been the major concerns for many organizations. Compared with traditional IT solutions, cloud computing has different threats concerns (Oktay and Sahingoz, 2013). According to (Ramteke, et. al, 2013), masquerade attack is one of the most critical attacks in the cloud. A masquerader is an attacker who authenticates as a legal user by stealing its credentials or by violating the authentication service (Kholidy, et. al. 2015). Several datasets are currently used to evaluate masquerade detection techniques, namely, SEA (Schonlau, 2017), Greenburg (Greenberg, 1988), Purdue

(Lane and Brodley, 1997), and CIDD (Kholidy and Baiardi, 2012). We used the dataset SEA to evaluate our masquerade detection algorithms in this paper.

Data in SEA contains username and the commands issued by those users. Compared with regular users, the commands issued by masqueraders have some sequential patterns, for example, changing users' privilege, accessing root directory and/or users directory, copying/deleting files, etc. Therefore we propose to use recurrent neural network (RNN) with Long short-term memory (LSTM) to detect masquerade attacks. RNN is a type of deep learning neural networks that can process sequential information using their internal state (memory). LSTM enables RNN to learn sequences containing longer-term patterns of unknown length. RNN with LSTM has been successfully applied in abnormal detection (Malhotra, 2015; Bontemps, et. al. 2016), network intrusion detection (Staudemeyer, 2015), human action recognition (Baccouche, M. et. al. 2011), etc. However, to the best of our knowledge, there has no research applying it to masquerade detection yet. To improve the performance of RNN, we adopted the method of preprocessing text data in text mining to transform the command list into word vectors. Experimental results showed that the modified RNN with Word Vectors (RNN-WV) performed well in detecting both the normal and masquerade records.

The contribution of the paper is twofold. Firstly, we innovatively applied RNN in masquerade detection to exploit the sequential patterns of user commands. Secondly, we used word vector to preprocess the commands to provide more exploitable information for prediction. The rest of the paper is organized as follows. We briefly review some related work in masquerade detection. Then we introduce the algorithms used for masquerade detection, including Multilayer Perceptron, RNN, and RNN-WV. Experiments, results and discussion are presented in the following section. The paper concludes with highlights and future work.

RELATED WORK

There has been many masquerade detection methods developed in the literature. Most of them are based on data mining algorithms. For example, Szymanski and Zhang (Szymanski and Zhang, 2004) used a SVM classifier to detects masqueraders. They first discovered frequent patterns in the sequence of user commands, encoded them with unique symbols, and then rewrote the sequence with the new coding for classification. Maxion and Townsend (Maxion and Townsend, 2002) applied a Naïve Bayes classifier to classify commands into either normal or masquerade. Naïve Bayes was also used in (Dash et al. 2005) to extract meaningful episodes from a long sequence of commands. Then a Naïve Bayes classifier was utilized to identify these episodes either as masquerade or normal.

Camina et. al. compared task-based Masquerade Detection System (MDS) with object-based MDS (Camina et. al. 2014). In order to evaluate the usefulness of the task abstraction, they designed some experiments with two different classifiers: Markov chains and Naïve Bayes. They found that a task-based MDS was as powerful as an object-based one. They also found that Markov chains outperformed Naïve Bayes, because it accounted for event temporal relationships.

Kholidy et. al. proposed a Data-Driven Semi-Global Alignment (DDSGA) approach for detecting masquerade attacks (Kholidy, et. al. 2015). In this approach, the user active session sequence was aligned to the previous ones of the same user and it labeled the misalignment areas as anomalous. A masquerade attack was signaled if the percentage of anomalous areas is larger

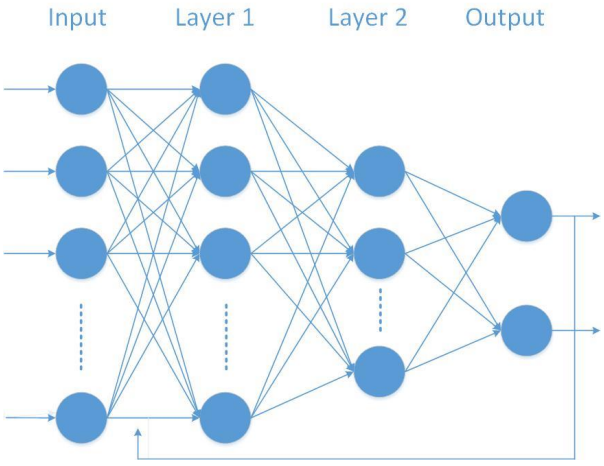
than a dynamic, user dependent threshold. Compared with SGA and other masquerade methods, DDSGA obtained higher hit ratio percent and relatively lower false positive percent. However, it could not effectively identify new masqueraders based on the commands of the existing users.

MASQUERADE DETECTION ALGORITHMS

Multilayer Perceptron (MLP)

A Multilayer Perceptron (MLP) was one types of the most frequently used artificial neural network (Rosenblatt, 1961). An MLP consists of at least three layers of nodes, an input layer, one or more hidden layers, and one output layer. Each layer consists of one or more neuron-like nodes. A node in one layer connects to nodes in the next layer. Except for the input nodes, each node is a neuron that uses a nonlinear activation function. MLP utilizes backpropagation for training. MLP can distinguish data that is not linearly separable. MLP was a popular machine learning solution in the 1980s, which has been successfully applied in the fields such as speech recognition, image recognition, and machine translation (Wasserman and Schwartz, 1988). Figure 1 shows the architecture of a MLP. In this paper, we use MLP as a baseline masquerade detection algorithm.

Figure 1: A Multilayer Perceptron (MLP)

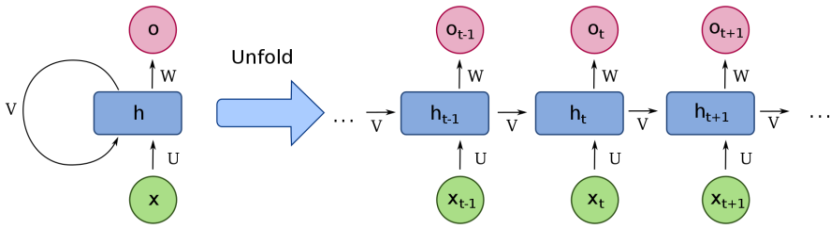


Recurrent Neural Network (RNN)

A Recurrent Neural Network (RNN) is neural network where connections between nodes form a directed graph along a sequence (Prasad, S. C. and Prasad, P., 2014). This allows it to exhibit dynamic temporal behavior for a time sequence. RNNs can use their internal state (memory) to process sequences of inputs. Basic RNNs are a network of neuron-like nodes, each is connected to other nodes in the next layer. Each node has a time-varying real-valued activation. Each connection has a modifiable real-valued weight. Like MLP, RNN usually is composed of an input layer, multiple hidden layer, and an output layer. For supervised learning in discrete time settings, sequences of real-valued input vectors arrive at the input nodes, one vector at a time. As shown in Figure 2, at any given time step, each non-input unit computes its current activation (result) as a nonlinear function of the weighted sum of the activations of all units that

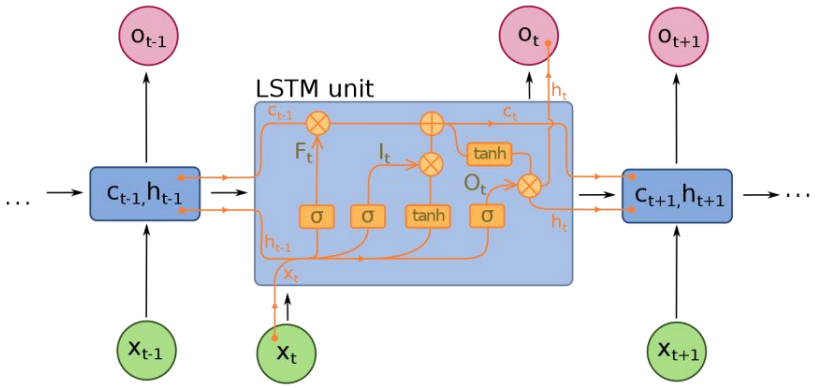
connect to it. Each sequence produces an error as the sum of the deviations of all target signals from the corresponding activations computed by the network. For a training set of numerous sequences, the total error is the sum of the errors of all individual sequences.

Figure 2: Unfolded basic recurrent neural network[1]



Long Short-Term Memory (LSTM) is used to avoid the vanishing gradient problem (Hochreiter and Schmidhuber, 1997). LSTM prevents backpropagated errors from vanishing or exploding. Instead, errors can flow backwards through unlimited numbers of virtual layers unfolded in space. That is, LSTM can learn tasks that require memories of events that happened thousands or even millions of discrete time steps earlier. LSTM works even given long delays between significant events and can handle signals that mix low and high frequency components. A long short-term memory unit is depicted in Figure 3.

Figure 3: Long short-term memory unit[1]



In this project, given a sequence of commands, we need to predict whether they are from a legitimate user or a masquerader. By applying RNN with LSTM, we utilize its memorizing feature to remember the signature command sequence from legitimate users and from masqueraders.

RNN with Word Vectors (RNN-WV)

To preprocess the commands to be fed to RNN with LSTM, instead of using a command stream, we adopted the method of preprocessing text data in text mining to transform the command list into word vectors. We built a command index and mapped each command to an

[1] By François Deloche - Own work, CC BY-SA 4.0, https://commons.wikimedia.org/w/index.php?curid=60109157

integer between 0 and the index size. Thus each command became a word vector and the command block became a input matrix. We believe this 2-dimentional structure provide more exploitable information for prediction.

EXPERIMENTAL RESULTS AND DISCUSSION

We conducted experiments to evaluate the performance of the proposed RNN methods for cloud masquerade detection.

Neural Network Setup

To compare the performance of the three neural networks mentioned before, we built the neural networks with similar structure. Figure 4 shows the architecture of MLP used in the experiments. It consists of three layers. The input layer has 100 nodes, which can input one block of 100 commands at a time. It has full connection to Layer 1, which also has 100 nodes. Layer 2 has 10 nodes, all of which connect to the output layer. The output layer has two nodes, which are used to denote whether the input block is a regular block (Class 0), or a masquerade block (Class 1).

Figure 4: MLP architecture used in experiments

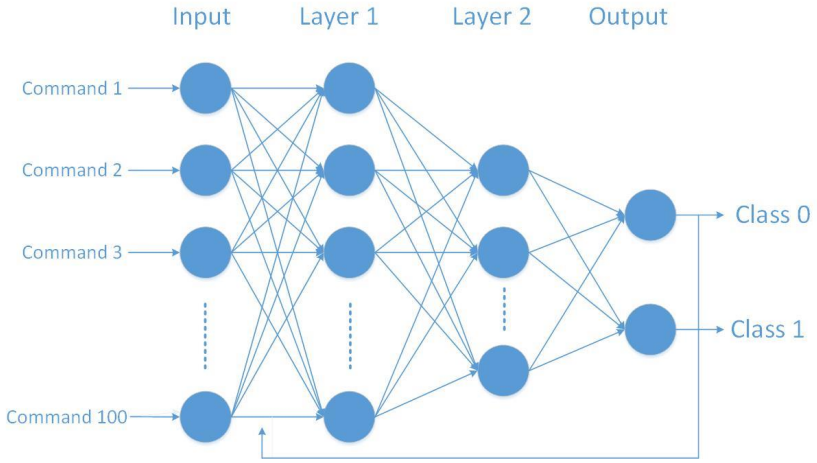


Figure 5 shows the architecture of RNN used in the experiments. It also consists of three layers. The input layer has only one node. The command block is considered as a univariate time series, which is input to the network one command per time step. It also has 100 nodes in Layer 1 and 10 nodes in Layer 2. The red circle under each node in these two layers represent the LSTM unit in the node.

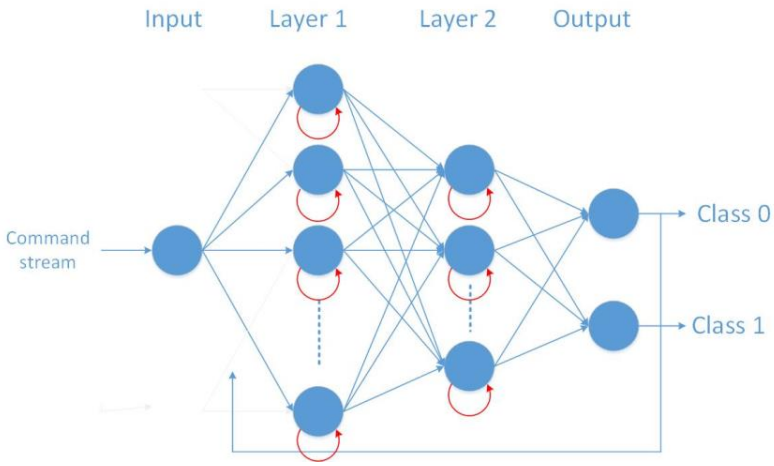
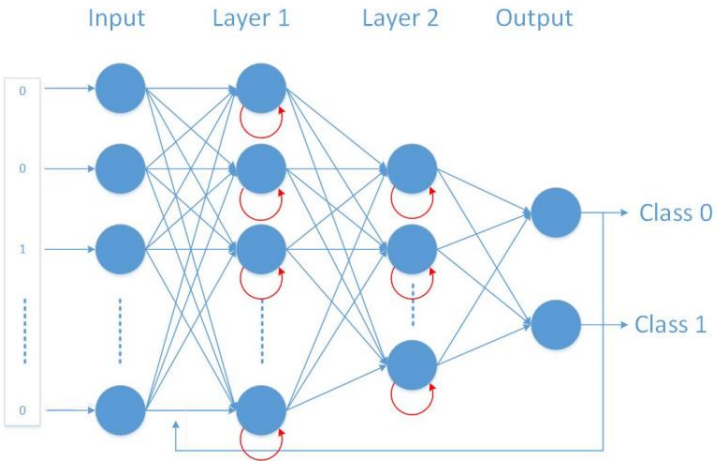
Figure 5: RNN architecture used in experiments



The architecture of RNN with word vector is shown in Figure 6. It has the same Layer 1, Layer 2, and Output Layer as the one in Figure 5. The only difference lies in the Input layer. It has multiple input nodes in this layer, and the number of input nodes depends on the number of commands in the dataset. The input is also considered as a time series data, but at each time step one word vector will be input to the network.

Figure 6: RNN with word vector used in experiments



Dataset

In this paper, we used SEA dataset (Schonlau, 2017), which was used by most papers on masquerader detection. SEA consists of commands collected from UNIX account audit data. Among all the fields of audit data only the username and the command were taken. The data describe 50 different users each issuing 15000 commands. The first 5000 commands are considered genuine. The remaining 10000 commands of each user are divided into 100 blocks of 100 commands each. These blocks are seeded with masquerade users. There is a 1% probability that a block is a masquerader and, in this case, there is a probability of 80% that the following one is a masquerader too. As a result, approximately 5% of the test data contain masquerades.

Metrics

We used the following metrics to measure the performance of the masquerade detection algorithms. We used *tp* to represent the number of true positive records, *tn* to represent the number of true negative records, *fp* to represent the number of false positive records, and *fn* to represent the number of false negative records.

Accuracy is the percentage of correctly predicted records over the total number of records.

$$Accuracy = (tp + tn) / (tp + tn + fp + fn)$$

Precision is the number of correct positive results divided by the number of all positive results.

$$Precision = tp / (tp + fp)$$

Recall is the number of correct positive results divided by the number of positive results that should have been returned.

$$Recall = tp / (tp + fn)$$

F_1 *score* can be interpreted as a weighted average of the precision and recall, where an F_1 score reaches its best value at 1 and worst at 0.

$$F_1 = 2 \cdot Precision \cdot Recall / (Precision + Recall)$$

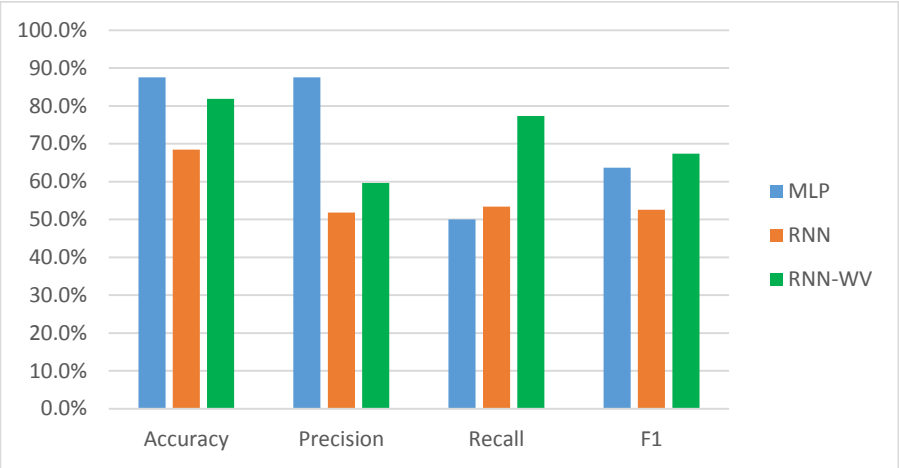
Performance Evaluation

We evaluated the performance of the masquerade detection algorithms in two scenarios, which are described below.

Scenario 1

In this scenario, we divided the data of each user into two parts, the training part and the testing part. We collected the training part data of all the users to train the neural networks, and then used the testing part data from all users to evaluate the prediction accuracy. The purpose of this scenario was to evaluate the performance of the predicting algorithm in identifying the masquerade behavior of existing cloud users. As only about 3% of the original dataset contains masquerade data, we under-sampled the dataset by removing the first 50 blocks of genuine data from each user. The performance of the masquerade detection algorithms was compared using the same under-sampled dataset.

Figure 7: Comparison of masquerade detection algorithms in scenario 1



As shown in Figure 7, RNN-WV performed better than RNN. Its overall accuracy is 81.9% while the accuracy of RNN is only 68.5%. The recall of RNN-WV is also more than 20% higher than RNN. Although MLP obtained better results than RNN and RNN-WV in accuracy, precision, and F_1, it actually failed the test. It was not able to identify any masquerade record. In other words, its recall is 0. We compared the recall results of all three algorithms in Table 1. Recall-Normal represents the percentage of the normal records that was correctly predicted, while Recall-Masq represents the percentage of the masquerade records that was correctly predicted. MLP reached 100% in Recall-Normal, which means it can correctly identify all the normal records. But on the other hand, its Recall-Masq value is 0%, which means it does not qualify for the masquerade detection task, as it cannot detect any masquerade record.

One reason MLP did not perform well was because the dataset was severely skewed, although the dataset was under sampled, the ratio of normal records to masquerade records was still 7:1. Another reason may be that the architecture of MLP was not sophisticated enough to handle this classification task. For comparison reason, we used the same hidden layers (Layer 1 and Layer 2) for all three neural networks. Table 1 also shows that the performance of RNN-WV was very promising. It successfully identified 82.5% of the normal records, and 72.2% of the masquerade records, which made it a good candidate for the masquerade detection task.

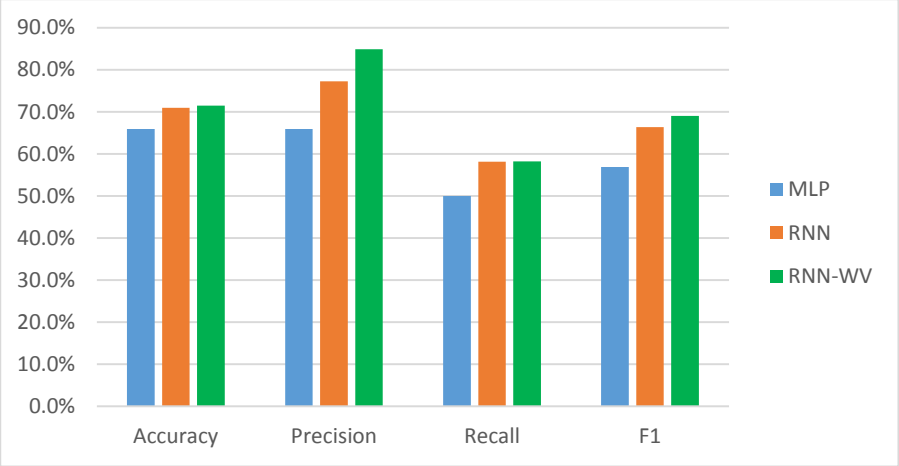
Table 1: Comparison of recall values in scenario 1

Measure	MLP	RNN	RNN-WV
Recall-Normal	100%	73.4%	82.5%
Recall-Masq	0%	33.3%	72.2%

Scenario 2

In this scenario, we divided the users into two groups, the training group and the testing group. We used the data from the training group to train the neural networks, and then used the data from the testing group to evaluate the prediction accuracy. This scenario was used to evaluate the performance of the predict algorithm in identifying the masquerade behavior of new cloud users. As in scenario 1, we under-sampled the dataset by removing the first 50 blocks of genuine data from each user. The performance of the masquerade detection algorithms was compared using the same under-sampled dataset.

Figure 8: Comparison of masquerade detection algorithms in scenario 2



RNN-WV still performs better than RNN and MLP in this scenario. Its overall accuracy is 71.5%. The performance of RNN is close to RNN-WV. And again, MLP classified all the records as normal records and failed to identify any masquerade records. Predicting the new user's behavior based on the behavior of the current users may be more difficult than predicting the future behavior of the existing users based on their previous behavior. That may be the reason why the performance of the three prediction algorithms was not as good as in scenario 1. As shown in Table 2, both RNN and RNN-WV could identify most of the normal records, but the accuracy of identifying masquerade records was below 20%. We will improve both algorithms to keep the current accuracy in predicting normal records and boost the accuracy in predicting masquerade records in our future work.

Table 2: Comparison of recall values in scenario 2

Measure	MLP	RNN	RNN-WV
Recall-Normal	100%	98.3%	100%
Recall-Masq	0%	18.0%	16.4%

CONCLUSION AND FUTURE WORK

Masquerade attack is one type of the critical attacks on the cloud. To detect masquerade attacks, we proposed to use RNN with LSTM to exploit the sequential feature of user commands. We also used word vectors in preprocessing to improve the prediction performance. The experiments showed that the RNN based methods outperformed the traditional MLP methods. Furthermore, the RNN with word vector method showed promising performance in identifying both the normal and masquerade records, which made it a good candidate for the masquerade detection task.

The experimental results also showed that the performance of predicting new masqueraders from the behavior of existing ones needed to be improved. We will modify the current algorithms to find a better solution.

One of most critical defects of dataset SEA is that SEA neglects command arguments and parameters. We will create a dataset with user profiles containing not only more detailed information about user commands, but also other user information such as login time, location, session, IP address, etc. We believe the new dataset will help build the masquerade detection system that can be applied to real-world cloud environment.

DECISION SCIENCES INSTITUTE
Value creation networks for Industry 4.0: best practices in German manufacturing industries

Sabine Baumann
Jade University of Applied Sciences
Email: sabine.baumann@jade-hs.de

ABSTRACT

While Industry 4.0 can open new business models by fulfilling vastly individualized customer requests, the design and implementation of value creation networks is challenging: the role of the focal firm as principal coordinator becomes increasingly decentralized, interface standards are missing, and big data analysis for the necessary real-time coordination bears algorithmic challenges. This paper presents results of a longitudinal meta-study on development and current state of Industry 4.0 in the German manufacturing industries. The author derives lessons learned and best practices for designing and implementing value creation networks in Industry 4.0 settings.

KEYWORDS: Industry 4.0, platforms, manufacturing industries, internet-of-things, value creation networks

INTRODUCTION

While Industry 4.0 can open new business models, the technical implementation and especially the value creation network design and the operations strategies for providing highly individualized products and services are challenging. The concept of Industry 4.0 no longer grounds in the idea of value creation networks as linear processes with specified beginnings, pre-determined process steps and a specific end. In its place, it requires full flexibility of value creation set-ups in order to fulfil vastly individualized customer requests (batch size of 1). To achieve this flexibility not only requires a set of actors that come together to bring that particular product or service to market, but their selection from a larger set of potential actors on a one-on-one basis. In particular, the role of the focal firm as coordinator and central decision maker becomes increasingly decentralized.
The objective of this paper is therefore to illustrate the origins of the Industry 4.0 concept and to investigate its evolution in the German manufacturing industries in the past five years. A case study on automobile manufacturing and interviews with industry executives provide insight on real-world challenges as well as lessons-learned from the introduction of industry 4.0 and related best practices for value creation network design and operations strategies.

LITERATURE REVIEW

The concept of industry 4.0

Origins
The term Industry 4.0 (I4.0) was coined by the German government in a high technology strategy project to address the increasing global competition on product quality and production costs faced by the German manufacturing industry (Lee et al. 2015; Müller et al. 2017; Rodriguez et al. 2018). I4.0 was first presented to the public at Hannover Industrial Fair 2011 as part of the High-Tech Strategy Action Plan 2020 (Helmold & Terry 2016). Germany's very

important manufacturing sector suffered through the relocation of production facilities towards aspiring countries, which had managed to close the productivity and quality gap while keeping labor costs comparatively low. At the same time, established manufacturing companies had to recognize that customers were no longer willing to pay large price premiums for incremental quality improvements and demanded customized products and fast delivery (Brettel et al., 2014; Helmrich 2017). Consequently, manufacturing companies started to exploit new business potentials and opportunities through emerging technologies such as digitalization, the internet of things (IoT), internet of services (IoS), or cyber-physical systems (CPS). Against this backdrop, Germany launched the Industrie 4.0 initiative as part of its high-tech strategy to establish itself as a leader of integrated industry. Since then, I4.0 has received growing attention (even keeping the original German spelling for the spelled-out variety of the term) and was recorded on the 2016 World Economic Forum's agenda (Hofmann & Rüsch 2017).

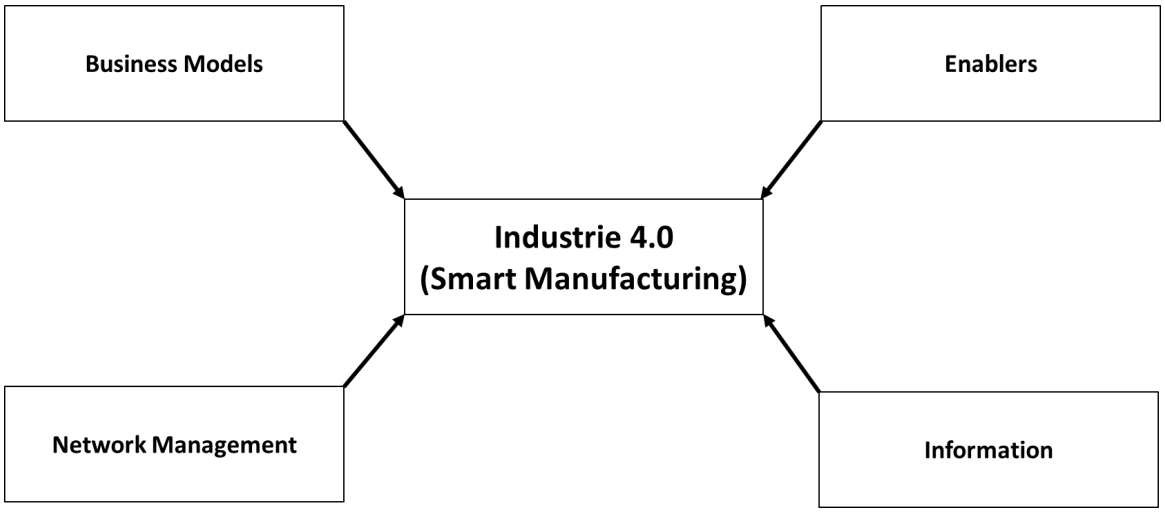
Definition

Most remarkably, although the concept Industrie 4.0 has been widely discussed for quite some time, there is still no generally accepted understanding of what it comprises, neither in academia nor in practice (Hofmann & Rüsch, 2017; Vogel-Heuser & Hess (2016), Xu et al., 2017). Interviews with practitioners commonly reveal a fuzzy image of I4.0 regarding the actual objectives, the relevant technologies, or the applicability for different industrial sectors. Similarly, academics have not developed a sound conceptual and terminological foundation of I4.0, which consequently hampers scientific research (Hermann et al., 2016).

Based on Spath et al. (2013), Bauernhansl et al. (2014) and Müller et al. (2017) this paper defines Industrie 4.0 as a concept in which companies, machines, devices and computers cooperate through digital technologies in horizontal and vertical networks to manufacture highly-individualized products. These networks continuously share information in real-time by connecting plants, equipment, machines, products and workpieces through information and communication technologies (ICT) into cyber-physical systems. As the concept of smart manufacturing conveys the same ideas as I4.0 (Kusiak 2017) both terms will be used interchangeably in this paper.

The author proposes to capture the I4.0 concept through four components: business models, enablers, information, and network management (see figure 1), which are subsequently explained.

Figure 1: Components of the Industry 4.0 concept



Business Models

From a business model perspective I4.0 either addresses cost reductions or capturing new business opportunities such as innovative products and services. Currently most manufacturers focus on the former while business model innovations are moving at a slower pace (Ernst & Young, 2017; Goschy & Rohrbach 2017; Rodriguez et al., 2018). Similarly, business models involving the creation platforms markets are still pursued with lower priority (Staufen AG 2018). The majority of new business models involve some form of data analytics. For analytic and predictive maintenance, the collected data is analyzed to offer customers improved information on process status or replacement suggestions for their equipment, hence adding a service component to the pure product (Staufen AG, 2018). Extended models move to a full service offer where the customer no longer buys the equipment, but only pays for equipment use (e.g. by volume or time). Essentially a service now replaces the product offer (everything as a service, XaaS).

From a cost reduction perspective, I4.0 is regarded as a means to improve processes or for increasing production flexibility and adaptiveness, faster reaction times, or an improved overall effectiveness of manufacturing equipment (Buer et al., 2018, Liao et al., 2016; Lu 2017).

Network Management

A major challenge is to determine the best real-time combination of actors regarding objectives such as timing, cost, quality levels, etc. for each individual order. Such a multitude of objectives can only be achieved through extended vertical, horizontal, and lateral collaborations resulting in growing complexities of value creation settings with multi-level competition and ensuing transaction costs (Baumann et al., 2016, Dietl et al., 2009, Holweg et al. 2014). As a result, actors face a trade-off between installing efficient value creation networks for particular products while being flexible enough to be part of alternative value creation networks for required product differentiations (Baumann et al., 2017, Brusoni et al., 2009, Jia et al. 2017, Pullman et al., 2010, Stevenson et al., 2017). In addition, the role of the focal firm as principal coordinator becomes increasingly decentralized in I4.0 settings. These challenges add to those discussed in the value creation network design and operations strategy literature (Holweg et al., 2014, MacCarthy et al., 2016, Pashaei et al., 2017).

Enablers

I4.0 grounds in a variety of enablers, which are briefly described in the following passage. A more detailed description and evaluation of I4.0 enablers can be found, for example, in Schebek et al. (2017) or Plattform Industrie 4.0 (2016).

Cyber-physical systems (CPS): CPS are systems that connect computation with physical processes. In the context of manufacturing this refers to monitoring and controlling the processes via computer networks (through the use of multiple sensors, actuators, control processing units, and communication devices) and synchronizing information related to the shop floor (Lee et al., 2015; Mosterman & Zander, 2016). Technologies such as RFID (radio-frequency identification) tags allow unique identification, while multiple sensors and actuators not only provide storage and data analytics, but are fully network compatible (Hermann et al., 2016). So-called manufacturing execution systems (MES) are the critical module that function as interoperational, real-time-enabled, and web-enabled connector between enterprise resource planning (ERP), production planning and control (PPC), and the actual shop floor, thus ensuring the connection of all network participants (Obermaier & Kirsch, 2017). Consequently, manufacturing equipment will turn into CPPS, Cyber-Physical Production Systems, which know their state, their capacity and their different configuration options and are also able to take decisions autonomously. In the I4.0 concept the shop-floor will become a marketplace of

capacity (supply) and demand for which multi-agent systems (self-)organize allocation (Almada-Lobo, 2016).
Internet of Things (IoT): The idea of smart, connected products is considered an initiator of Industry 4.0. IoT refers to a setting where essentially all (physical) things can turn into so-called smart things by featuring RFID tags, sensors, actuators, or small computers that are connected to the internet (Keskin & Kennedy, 2015). Through unique addressing schemas, these components interact with each other and cooperate with their neighboring 'smart' components in order to reach common goals (Hermann et al., 2016). IoT is at the heart of business models relying on new functionality, improved reliability, higher product utilization and capabilities (Greiner, 2015; Hofmann & Rüsch, 2017).
Internet of Services (IoS): The idea behind IoS is to make services easily available through web technologies (such as service-oriented architecture (SOA) or software as a service (SaaS)). allowing companies and consumers to create new kinds of value-added services. These services provide access to the resources of another party in order to perform a prescribed function and receive a related benefit. Resources may be human workforce and skills, technical systems, information, consumables, land, etc. (Hofmann & Rüsch, 2017).
Smart factory: The idea of the smart factory conveys a decentralized production system that is made up of a network of human beings, machines and resources that communicate with each other as naturally as in a social network (Yin et al., 2017. The existing production logic with a central steering entity changes towards smart products that navigate their way independently through production processes and are easily identifiable and locatable at any time. Digital connectivity enables an automated and self-optimized production of goods and services including delivering without human interventions (self-adapting production systems based on transparency and predictive power) (Hofmann & Rüsch, 2017). Besides these changes in production processes also the roles of employees are expected to alter with employees taking on more supervising tasks with greater responsibility (Spath et al., 2013). They are supported by smart technologies such as wearables (e.g. smart watches, glasses, or gloves), augmented reality applications, autonomous vehicles (incl. drones) and distributed ledger systems (e.g. the blockchain) (Xu et al., 2018). Data analytics amalgamates the information from these connected systems to provide decision support to both machines and humans (Ainin et al, 2015; Ba & Nault, 2017).

Information
I4.0 depends on extensive data analytics (Yin et al., 2017) and, increasingly, concepts of Artificial Intelligence (AI) and Machine Learning (ML) (Staufen AG, 2018; Wunck & Baumann, 2017). In a first process step data is being collected via multiple devices equipped with sensors. Data analytics then inspects, cleanses, transforms, and models data in order to discover patterns, extract relevant information, and support decision-making. Typical techniques involve data mining, which mostly focuses on data analysis for predictive purposes, and statistical applications, which focus on discovering previously unknown facts, structures, or evidence (Ba & Nault, 2017). Other common techniques are data visualization and data dissemination (Ainin et al, 2015). Big Data, i.e. data that is challenging through its volume, variety, velocity, and/or veracity, proves particularly challenging in data analytics, as these big data sets typically exceed the capabilities of traditional data-processing application software (Baumann & Eulenstein, 2014). Furthermore, it is important to evaluate the information processing chain regarding the value added by its process steps. A reference process model for industrial IoT applications can compare the value propositions of competing solutions (Wunck & Baumann, 2017).

DESIGN/METHODOLOGY/APPROACH

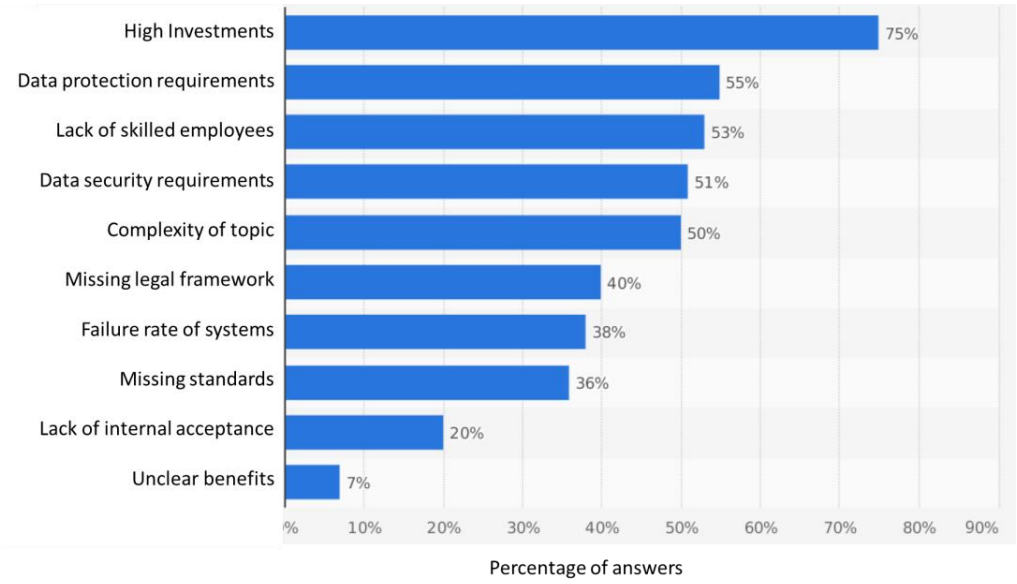
In a longitudinal meta-study, the author traces the development of the Industry 4.0 concept and its implementation in the German manufacturing industry over a period of five years based on archival data, case studies from the automobile industry and a medium sized (plastics) manufacturer, semi-structured interviews, and field observations. Germany was selected as the concept originates in this country. This paper focuses on presenting a condensed overview of the results of the meta-study and the automobile industry case study.

RESULTS

Industry 4.0 lessons learned from German industry

Optimistic studies estimate German manufacturers on average can nearly double their operating profit through smart manufacturing (Cap Gemini Consulting, 2018). At the same time manufacturers become gradually aware that technological changes do not only bear great potential, but do come with considerable risks of disruption. Almost 60% of manufacturers anticipate disruptive attacks in the next ten years (Goschy & Rohrbach, 2017). Consequently, increasing investment into I4.0 technologies is expected for the near future, particularly for SME. On average 5% of turnover will likely be invested, primarily for personnel and ICT. In terms of outcomes the highest potential is expected for increasing flexibility in production and logistics (Ernst & Young, 2017), predictive maintenance on both the production and product side (Goschy & Rohrbach, 2017), and the development of new business models (Bundesministerium für Wirtschaft und Energie, 2015; Helmrich, 2017).

Figure 2: Impediments to I4.0 for German manufacturers (Bitkom Research, 2018)



Surprisingly, the majority of German companies do not yet have a digitalization strategy (Gelowicz, 2018) and only a quarter have an advanced digitalization state of their vertical and horizontal value creation chains (Budak et al., 2018). Studies into reasons why I4.0 is not implemented a faster rate (see figure 2) reveal that German SME in particular shy away from the extensive investments into technology and personnel (Ernst & Young, 2017) and are more

concerned about the costly complexity of the tasks and data security issues than larger organizations. SME have limited available resources and also have to address integration of their legacy equipment into I4.0 scenarios (Bundesministerium für Wirtschaft und Energie, 2015, Staufen AG 2018).

So what are the success factors for I4.0 and what lessons can be learned from German industry? The first lesson is about *customer focus* and *service-oriented business models*. Companies need to satisfy vastly heterogeneous customer needs while balancing the trade-off in realizing scale effects along the value chain through standardization and mass production (Baumann et al., 2017). An efficient implementation of I4.0 supports the move towards mass customization that focuses on the production of personalized mass products, mostly through flexible processes, modularized product design and integration between supply chain members along the value chain. Otherwise high-wage countries such as Germany cannot compensate their inferior labor cost structure when barriers to entry diminish for new competitors (Brettel et al., 2014; Helmrich, 2017) and boundaries between producers, suppliers and customer become increasingly blurry (Ernst & Young, 2016). In addition, new businesses emerge that complement the traditional sale of machinery and products with smart services such as predictive maintenance (Goschy & Rohrbach, 2017).

The second lesson concerns the *design of collaborative production and supply networks*. It is vital to accommodate the strategic planning level decisions of shifting added-value creation from one factory or company towards integrated production and supply networks with an ensuing complexity of products and processes. This involves the design of the aggregated flows of materials and products among suppliers and facilities not only from a procurement point of view, but also from a distributional perspective towards customers (Altmann, 2015). These value creation networks offer a number of advantages: risk sharing, pooling of resources, expansion of market opportunities, and overall a more agile adaptation to volatile markets and shortened product lifecycles. However, the decoupling and spatial separation of production processes comes with high costs for coordination, synchronization, and cross-company data sharing and integration (Baumann et al., 2017; Brettel et al., 2014; Lödding et al., 2017). Furthermore, different mentalities towards information and cost-sharing as well as opportunistic behavior can deteriorate or even destroy the benefits of the collaboration network. Therefore, adequate control measures across all production- and supply-related actors need to be operationalized by formal safeguards to manage the complexity of the networks (Dietl et al., 2009).

The third lesson lies in *Data Management*. The success of I4.0 scenarios depends on the availability, adequate processing and distribution of the necessary information for the efficient steering of the collaboration networks. These data come from ERP-systems, product sensors, machine data as well as production information (e.g. runtime, capacity usage, order status) across all network partners (Wunck & Baumann, 2017). The value, however, does not lie in collecting the data, but in amalgamating and analyzing it for the entire network in order to propose the best possible combination of network partners for a particular customer request (Baumann et al., 2017). Likewise powerful analyses are needed for real-time predictions, e.g. for predictive maintenance or system status, to provide smart services to the customers. However, algorithmic challenges inhibit data exploitation, in particular in settings with polynomially or exponentially growing run-time (Baumann & Eulenstein, 2014).

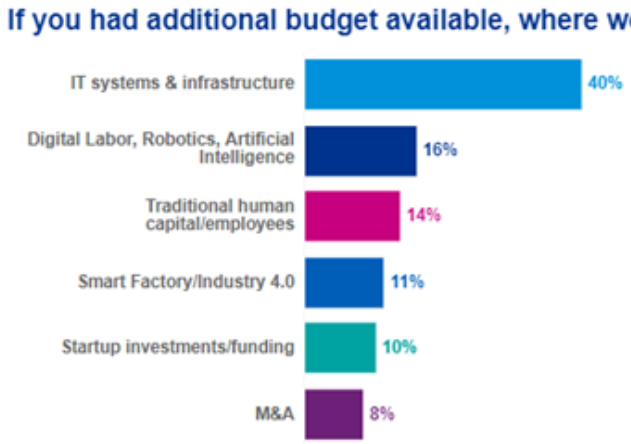
Finally, it has to be noted that the major challenge of I4.0 is not the technology, but the *management of the digital transformation process* including the design of value creation networks (Mason & Wagner, 2005). Managers often underestimate the speed of the transformation and as a result necessary organizational structures and cultures are not being implemented with adequate speed (Goschy & Rohrbach, 2017, Staufen AG, 2018). Even more seriously, the majority of German manufacturing companies have not even started to develop an I4.0 roadmap that is grounded in a cross-functional and agile digitalization strategy

(Sniderman et al., 2016). Neither, are the benefits of collaboration networks explored in depth nor those of innovative business models (Bundesministerium für Wirtschaft und Energie, 2015; (Goschy & Rohrbach, 2017); Plattform Industrie 4.0, 2016).

Case Study: Industrie 4.0 in automobile manufacturing

The automobile industry is among the most important industrial sectors in Germany and hence has a strong influence on overall economic development. Its competitive environment is characterized by increasing dynamics and volatility combined with a market saturation in voluminous core markets (USA, Europe or Japan) as well as an intensifying price competition. Furthermore, the industry experiences shorter product life cycles and growing customer demand for individualized products (Gölzer & Fritzsche, 2017; Hung Vo, 2016) which leads to a high diversification of products through variants and customer-specific fittings. Manufacturers have addressed these challenges by reducing vertical integration and shifting activities to their suppliers (Reinhart et al., 2017). Consequently, both product and process complexity have vastly expanded within the automotive industry (Hung Vo, 2016). In addition, market developments such as shared-ride and car sharing models have demonstrated the disruptive power of digital business models. This setting calls for I4.0 scenarios and it is hardly surprising that the automotive industry is one of the forerunners. Almost all German companies in this industry already work with smart manufacturing concepts or explore digital additions to their business models (Goschy & Rohrbach, 2017).
Current car buyers expect they can configure all possible features of their automobile ranging from color to seats, engines, tires and audio-visual equipment. Digitization will soon allow customers to change the color of their vehicle up to the moment the car body enters the paint shop. Digital features will change future user experiences with the car reminding the driver that the next inspection is due based on actual wear and tear or the manufacturer being able to keep in touch via personalized audio-visual messaging. Sensors will provide manufacturers with extensive data sets on actual car usages and performance which can be analyzed to improve future car design (Helmrich, 2017). Data analytics also provides entirely new business models around upstream data usage, offering paid services during the product-lifetime. This is particularly interesting for the high-volume manufacturers that have lower profit margins in the traditional point of sales model (KPMG, 2018).

Figure 3: Investment in the automotive industries (KPMG, 2018, p. 8)



Production systems at German automobile manufacturers are being redesigned to handle the complexity induced by the market (Dunckern, 2017). Other requirements are to further improve productivity of production (e.g. costs, time, quality), but also an increased flexibility to produce more variants and to address the ensuing complexity (Reinhart et al., 2017). However, it is important to note that German automobile manufacturers do not expect a batch size of 1 as propagated by I4.0 purists. Manufacturers perceive it as either irrelevant or not feasible for implementation in their current market environments (Goschy & Rohrbach, 2017). They also have no intention of deviating from the focal firm concept, contrary to what is propagated for I4.0.
All I4.0 enablers and technologies such as IoT, CPS, artificial intelligence, human-robot-collaboration, virtual and augmented reality, driverless transport systems, RFID, additive manufacturing or drones have or are about to become standards in German automobile production (Brettel et al., 2014). IoT in particular is regarded as an important enabler for information sharing across participants in collaboration networks (Tietze et al, 2017). Every new car is now a part of the IoT and vehicles are communicating with each other, and sending and receiving data via the cloud. The technology supports, for example, lane compliance, parallel parking or setting insurance premiums according to driver capability.
Looking ahead it is interesting to note that a surprisingly high share of automobile executives (40%) would invest into IT systems & infrastructure rather than into I4.0. However, this could also be an indicator that executives perceive a homogenous IT as necessary prerequisite for I4.0 to be fully implemented (KPMG, 2018, Staufen AG).

CONCLUSION

The results of the meta-study show that the implementation of the Industry 4.0 can vary depending on the industry and the size of the company. Large automobile manufacturers are fairly advanced in collaborating with suppliers, yet real-time routines for assessing and integrating actors into the supply network are still underdeveloped. Beyond that, SME also struggle considerably with understanding the implications for their business models. Fully adaptive value creation design consequently still lags behind the original propositions as do real-time data exploitations. Most notably, many existing studies do not or only superficially address the business model level, thereby neglecting the question of how the considerable costs of realizing Industry 4.0 can be recouped from increased sales.
This paper adds knowledge on designing value creation networks and operations strategy for Industry 4.0 settings when moving away from focal firms to more decentralized procedures, including competitive challenges in and between networks. Current findings indicate, however, that executives do not regard full decentralization of decision making as an option, but prefer to manage networks in focal position for the relevant segments of their value creation networks.

Value or Volume?
A Comparison of Two Risk Sharing Approaches

ABSTRACT

We compare a sales volume-based agreement and a value-based cost-effectiveness rebate between a payer and manufacturer to deal with uncertainties in new and expensive pharmaceutical products. We find the conditions in which the two parties agree or disagree on the preferred contract. Our study suggests that the contract preferred by the two parties depends on a combination of factors such as the drug price, treatment eligibility, etc. To our knowledge, our study is the first modelling paper on the direct comparisons between the two contracts which generates important insights and provides foundations for future design and selection of the contracts.

KEYWORDS: Risk-sharing, Price volume agreement, Cost-effectiveness, Drug costs, Pharmaceutical promotions

INTRODUCTION

The large proportion of pharmaceutical spending in both health expenditures and gross domestic product is a big concern in many countries. For example, 20% of health expenditures were spent on pharmaceuticals in Organization for Economic Co-operation and Development (OECD) countries in 2013 (Organisation For Economic & Development, 2015). Many payers use a formulary (a list of drugs that will be reimbursed by the payer) to manage and contain pharmaceutical spending (Gershon, 2011; Zaric & Xie, 2009).

However, when making formulary listing and reimbursement decisions, there are several uncertainties such as the sales volume or the effectiveness of new drugs. Sales volumes could be larger than originally anticipated due to factors such as poor forecasts, off-label usage, expansion of indication, and marketing effort by the manufacturers (Zhang, Zaric, & Huang, 2011). The effectiveness of new drugs in real clinical practice could be lower than the efficacy in clinical trials which usually have targeted patients with higher adherence level (Antonanzas et al., 2011). To deal with these uncertainties many payers have adopted risk-sharing agreements under which the reimbursement for a pharmaceutical product is related to its performance in real-world settings (Adamski et al., 2010).

Although the uncertainties in both sales volume and health outcome co-exist in many situations, we are not aware of any direct theoretical comparisons between sales volume-based and health outcome-based contracts. Our study intends to fill an important gap by comparing the performance of a sales volume-based agreement and a cost-effectiveness-based agreement to provide theoretical foundations for selection and decision making in the future. We focus on the comparison between a sales volume-based agreement and a value-based cost-effectiveness rebate.

To control financial expenditure, a price volume agreement (PVA) uses a sales threshold, and manufacturers must pay partial or full rebate to payers for excessive sales over the threshold. These contracts are widely used in Australia and many European countries (Adamski et al., 2010). To manage the uncertainties in health outcomes, a value-based cost-effectiveness rebate (CER) specifies a cost-effectiveness threshold and manufacturers have to pay rebates to payers if the drug fails to meet the benchmark (Adamski et al., 2010). A well-known example of this type of plan was in the listing for Multiple Sclerosis drugs in the UK (Palace et al., 2015).

Several studies have investigated the performance of a PVA (Zaric & O'Brien, 2005; Zhang & Zaric, 2011, 2015; Zhang et al., 2011) and some examined the efficiency of a CER (Antonanzas et al., 2011; Barros, 2011). Limited studies compared different types of risk sharing agreements. For example, Zaric and Xie (2009) compared two cost-effectiveness-based agreements and showed that the optimal agreements for the two parties depend on several factors and neither of them is always preferred by either party (Zaric & Xie, 2009). Levaggi (2014) compared the welfare of a listing through an uncertain bargaining process and a value based pricing agreement with risk sharing, and showed that the total welfare is always better under a value-based pricing scheme but the distribution of the benefits between consumers and the manufacturer depends on the rebate rate (Levaggi, 2014).

We are not aware of any direct comparisons between a sales volume-based and a health outcome-based agreement. In this study, we build a model which consists of a manufacturer and third-party payer to compare the desirability of a PVA and a CER. It should be noted that the two contracts under comparison are not always applicable in reality. For example, a CER is not an option when outcome is not measurable or there is generic alternative available. However, our study intends to provide insights into situations where both contracts are available options and need to be compared. We model the manufacturer's marketing efforts explicitly as it can significantly affect both the cost-effectiveness and the sales volume of a new drug. To our knowledge, our study is the first modelling paper on the theoretical comparison of the two risk-sharing approaches.

MODEL

We develop a model to analyze interactions between a public third-party payer (payer) and a pharmaceutical manufacturer (manufacturer). We assume the manufacturer has received regulatory approval to sell a new drug and has applied to the payer to list the drug on the formulary. To manage the uncertainties in the sales volume and health outcome of the new drug, the payer is considering one of two risk-sharing agreements (i): a price volume agreement ($i = PVA$), and a value-based cost-effectiveness rebate ($i = CER$). All model notation is summarized in Table 1.

Without loss of generality, we normalize the size of the patient population to one. Let β be the incremental health benefit for a patient using the new drug compared with the current standard

Table 1 Summary of notation

Decision	
Manufacturer	
m	Marketing effort
Payer	
i	Index for the two contracts, $i = PVA, CER$
Parameters	
β	Incremental health benefit per patient under the new drug compared with the current standard treatment
$\underline{\beta}, \overline{\beta}$	Lower bound and upper bound of β
$f(\cdot), F(\cdot)$	PDF and CDF of β
λ	Payer's willingness to pay threshold
y	Threshold (lower bound) of treatment eligibility for the new drug
ϵ	A random variable for heterogeneity in prescribing behavior
$\underline{\epsilon}, \overline{\epsilon}$	Lower bound and upper bound of ϵ
$g(\cdot), G(\cdot)$	PDF and CDF of ϵ
k	Parameter of the efficiency of the marketing effort in the cost function
p	List price of the new drug
c_M	Manufacturer's marginal production cost per unit of drug
c_P	Payer's non-drug related cost per unit of drug
a_P^i	Payer' implementation cost of contract i per unit of drug
x	Volume threshold for rebate in a PVA
Calculated quantities	
Q	Expected total sales of the new drug.
B	Expected total health benefit of the new drug
S^i	Expected total rebate in contract i
π_M^i	Manufacturer's expected profit
π_P^i	Payer's expected payoff
Other notation	
$*$	Superscript for optimal value

of treatment. The units of β could be quality-adjusted life years (QALYs), life years (LYs) or any other units that the payer cares about. We assume patients are heterogeneous in β between $\underline{\beta}$ and $\overline{\beta}$ according to a probability density function (PDF) $f(\cdot)$ and a cumulative distribution function (CDF) $F(\cdot)$. (i.e., different patients derive different levels of benefit relative to the standard of care). This captures the variability across patients that can be attributed to patient characteristics or other factors. Let λ be the payer's willingness to pay for each unit of β.

We assume that there is a threshold of treatment eligibility y such that all patients with $\beta \geq y$ will be treated with the new drug, and patients with $\beta < y$ will be treated with the current standard of care. The parameter y is exogenous and specified in clinical or formulary guidelines and is thus interpreted as a rule that only patients expected to derive a minimal level of benefit will be prescribed the new drug. We assume that physicians can observe β for each patient prior to the prescribing decision, and that each patient consumes one unit of the new drug if prescribed.

There is heterogeneity in prescribing decisions which can be caused by physicians' inability to perfectly observe β, differences in interpretations of guidelines, situations which are not adequately captured by the guidelines, off-label use and "indication creep" (Cabana et al., 1999;

Lugtenberg et al., 2009; Riggs & Ubel, 2015). Therefore, some physicians may prescribe the new drug to patients who are not eligible according to clinical guideline whereas others may prescribe the new drug more strictly. Let ϵ be a random variable distributed between $\underline{\epsilon}$ and $\overline{\epsilon}$, with a PDF $g(\cdot)$ and CDF $G(\cdot)$, that captures heterogeneity in prescribing behavior. In addition, the manufacturer exerts marketing effort $m > 0$ at a cost of km^2 to increase demand, where k is the parameter of the efficiency of the marketing effort. Typical marketing effort include detailing, giving free samples to physicians and advertising in medical journals (Hébert & Stanbrook, 2007; Mizik & Jacobson, 2004). The cost function is similar to those used in some other studies on advertising (Bagwell, 2007; Tirole, 1990) and has the following properties: 1) marketing effort can only increase sales, 2) there is diminishing marginal returns on marketing effort, 3) no cost will occur without marketing effort. We assume that the mechanism of the marketing effort is to cause physicians to prescribe the new drug to some patients who are not eligible according the original clinical guideline, which has the effect of reducing the treatment threshold to $y - m$. The combined effect of heterogeneity in prescribing decisions and manufacturer promotional effort is that the actual treatment eligibility is $y - m + \epsilon$. Thus, the total sales quantity of the drug is $q = \int_{y-m+\epsilon}^{\overline{\beta}} f(\beta)d\beta$, the total health benefit of the drug is $b = \int_{y-m+\epsilon}^{\overline{\beta}} \beta f(\beta)d\beta$, the expected total sales quantity over ϵ is $Q = \int_{\underline{\epsilon}}^{\overline{\epsilon}} q\, g(\epsilon)d\epsilon$, and the expected total health benefit of the drug is $B = \int_{\underline{\epsilon}}^{\overline{\epsilon}} b\, g(\epsilon)d\epsilon$.

Let p and c_M, $p > c_M > 0$, be the price and the manufacturer's marginal production cost per unit of drug, respectively. Let c_P be the payer's non-drug related incremental cost per unit of drug which could be positive or negative. A negative c_P indicates that the new drug causes a reduction in non-drug healthcare expenditures. For example, the drug may prevent or delay expensive surgeries, or prevent infections that are expensive to treat. A positive c_P indicates that the new drug causes an increase in non-drug healthcare expenditures. For example, it may be necessary to administer the drug in hospital, or spend time in hospital to treat a drug reaction. Let a_P^i be the administration cost for implementing contract i which is assumed to be fully borne by the payer. The payer's monetary benefit is $MB = \lambda b - (p + c_P + a_P^i)q$. The first term λb denotes the monetary value that the payer attached to the total incremental health benefit of the new drug. The second term $(p + c_P + a_P^i)q$ is the total costs incurred by the payer.

Let s^i be the rebate from the manufacturer to the payer under contract i. In a PVA, a sales threshold x is predetermined in the contract and we assume that the manufacturer must pay full rebate to the payer for the excess of sales, i.e. $s^{PVA} = \max\{0, p(q - x)\}$. In a CER, there is no rebate when $MB \geq 0$, and the manufacturer must fully compensate the payer's loss if $MB < 0$, i.e. $s^{CER} = \max\{0, (p + c_P + a_P^{CER})q - \lambda b\}$. Let S^i be the expected value of s^i over ϵ.

Let π_P^i and π_M^i be the payer's and the manufacturer's expected payoff under contract i which are calculated as follows

$$\pi_P^i = \lambda B - (p + c_P + a_P^i)Q + S^i \quad (1)$$

$$\pi_M^i = (p - c_M)Q - km^2 - S^i \quad (2)$$

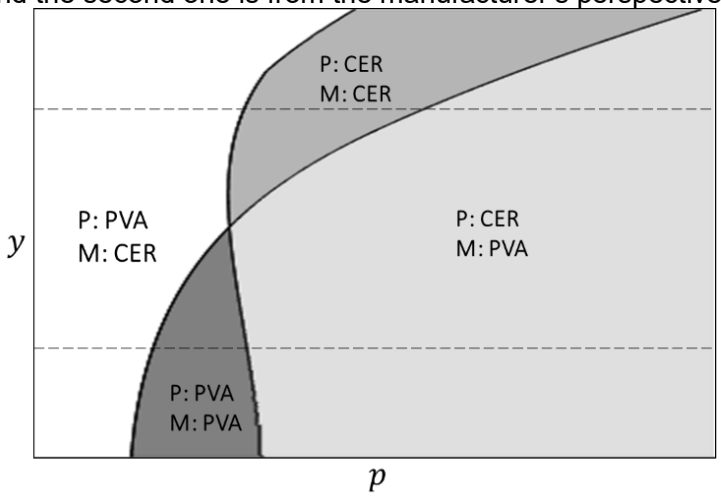
We assume that the payer first chooses the optimal risk-sharing agreement i to maximize her expected payoff and then the manufacturer chooses the optimal marketing effort m to maximize his expected payoff. The payer will choose a PVA if the expected payoff in a PVA is greater

than the payoff in a CER, i.e. $i_P^* = PVA$ if $\pi_P^{PVA*} > \pi_P^{CER*}$, and vice versa. Similarly, the manufacturer prefers a PVA if the expected payoff in a PVA is greater than the payoff in a CER, i.e. $i_M^* = PVA$ if $\pi_M^{PVA*} > \pi_M^{CER*}$, and vice versa. We do not consider any participation constraint for the payer as her payoff is always non-negative in a CER according to the setup of the rebate, and therefore π_P^{CER} could be considered as the reservation payoff for the payer. Thus, the payer will not choose a PVA if $\pi_P^{PVA} < 0$.

ANALYSIS

We made some additional assumptions in order to derive analytical solutions. We assume β is uniformly distributed between 0 and 1 and ϵ is uniformly distributed between $-\overline{\epsilon}$ and $\overline{\epsilon}$, $\overline{\epsilon} > 0$. Later we perform a robustness check and find that the main results also hold for normal distributions. We assume that the rebate threshold in a PVA is exogenously set equal to the expected sales (i.e. $x = Q$) since many PVA's set the sales limit based on anticipated expenditure (sales) (Adamski et al., 2010). With these additional assumptions, we find the optimal marketing effort (m^*), the payer's and the manufacturer's expected payoff in contract i (π_P^{i*} and π_M^{i*}, respectively) which are summarized in Table A1 and Table A2 in the appendix. We present the findings numerically using parameter settings $\lambda = 50000, \overline{\epsilon} = 0.1, c_M = 5000, c_P = 500, a_P^{PVA} = 200, a_P^{CER} = 1000$ and $k = 10000$. We also perform a robustness check on different values of the administration costs as it is one the major concerns of implementing a risk-sharing agreement (Adamski et al., 2010) and find that our results are qualitatively similar over a wide range of possible values.

Figure 1: Two-way policy graph of the contracts preferred by the payer and the manufacturer (the first contract in the labels is the optimal contract from payer's perspective and the second one is from the manufacturer's perspective)



In Figure 1, we present a two-way policy graph for the contract preferred by each party for different combinations of the drug price p (horizontal axis) and the treatment eligibility y (vertical axis), as preliminary analysis demonstrates that the optimal solutions are sensitive to these two parameters. The lower dashed line is for a small value of y which corresponds to a broad treatment eligibility, and the upper dashed line is for a large value of y which corresponds to a targeted treatment eligibility. With a sufficiently low price, the payer prefers a PVA, but the manufacturer prefers a CER. When price is sufficiently high, the payer prefers a CER, but the

manufacturer prefers a PVA. For intermediate prices, the two parties may prefer the same contract depending on the combinations of parameters. In this numerical example, both parties prefer a PVA when treatment eligibility is broad (i.e., y is low); and both prefer a CER when treatment eligibility is targeted (i.e., y is high). When prices are very big or very low the two parties disagree on the preferred contract.

To explain the logic behind Figure 1, we present additional details in Figures 2 and 3 corresponding to combinations of p and y shown along the two dashed lines in Figure 1. Figures 2 (a) and (b) show that with both broad and targeted treatment eligibility, the marketing effort in a PVA is greater than in a CER, and the marketing effort in a PVA is increasing in the drug price whereas the marketing effort in a CER is non-monotonic (increasing then decreasing) in the drug price. Figures 2 (c) to (f) show that the expected total sales and total health benefit of the new drug have the same trend with the optimal marketing effort. These trends are interrelated with the changes in the optimal rebate which are explained in the next paragraph.

Figures 2 (g) and (h) show that in the optimal solution, there is always a positive expected rebate in a PVA. This is because the manufacturer has to pay a rebate to the payer when there are excessive sales but does not receive any reward from the payer if the total sales is below the sales limit. The manufacturer is able to increase the marketing effort as the rebate is relatively small, and the increased profit from the increased marketing effort outweighs the marketing cost and rebate. In a CER, when price is sufficiently lower than the payer's willingness to pay, there is a higher chance that the monetary value of the total health benefit λb exceeds the payer's costs $(p - c_P - a_P^{CER})q$ and thus the optimal rebate is zero. This is because the relationship between the two quantities is dominated by the large difference of the drug price and the willingness to pay. The relative change in the total sales and total health benefit is relatively small as both quantities have same trends as shown previously (Figures 2 (c) to (f)). As a result, the manufacturer could increase the marketing effort to increase drug sales and profit without concern about the rebate in this price range. When price is sufficiently high, the optimal rebate in a CER starts to increase in the drug price. This is because the payer's costs are more likely to exceed the monetary health benefit which is again dominated by the relationship between the price and the payer's willingness to pay. Thus, the manufacturer makes a trade-off between the increased sales and rebate, and the optimal marketing effort is decreasing in the drug price in this price range.

Figure 3 shows the two parties' payoffs as a result of the combined effect of the aforementioned optimal quantities. Let $\tilde{p}_P$ be the switching price where the payer's preferred contract switches from a PVA to a CER and let $\tilde{p}_M$ be the switching price where the manufacturer's preferred contract switches from a CER to a PVA. Figures 3 (a) and (b) show that the payer prefers a PVA with a sufficiently low drug price ($p < \tilde{p}_P$). This is because the rebate in a PVA is positive but the rebate in a CER is zero (as shown previously in Figures 2 (g) and (h)) and this difference in rebate outweighs other differences between the two contracts such as monetary health benefit and profit from marketing effort and total sales. When price is sufficiently high ($p \geq \tilde{p}_P$), the payer prefers a CER as the rebate in a CER is increasing rapidly with price and exceeds the rebate in a PVA. Similarly, Figures 3 (c) and (d) show that the manufacturer prefers a CER with a low drug price ($p < \tilde{p}_M$) and prefers a PVA with a high drug price ($p \geq \tilde{p}_M$). Define the switching patients as those who are treated with the new drug but who would not be treated without marketing effort. With a broad treatment eligibility, the incremental health benefit from the switching patients is small, which reduces the manufacturer's switching price and creates a range for a PVA to be preferred by the two parties. With a targeted treatment eligibility, the incremental health benefit from the switching patients is large. This allows a health outcome-

Figure 2 Optimal values when y is small (the lower dashed line in Figure 1) and y is large (the upper dashed line in Figure 1)

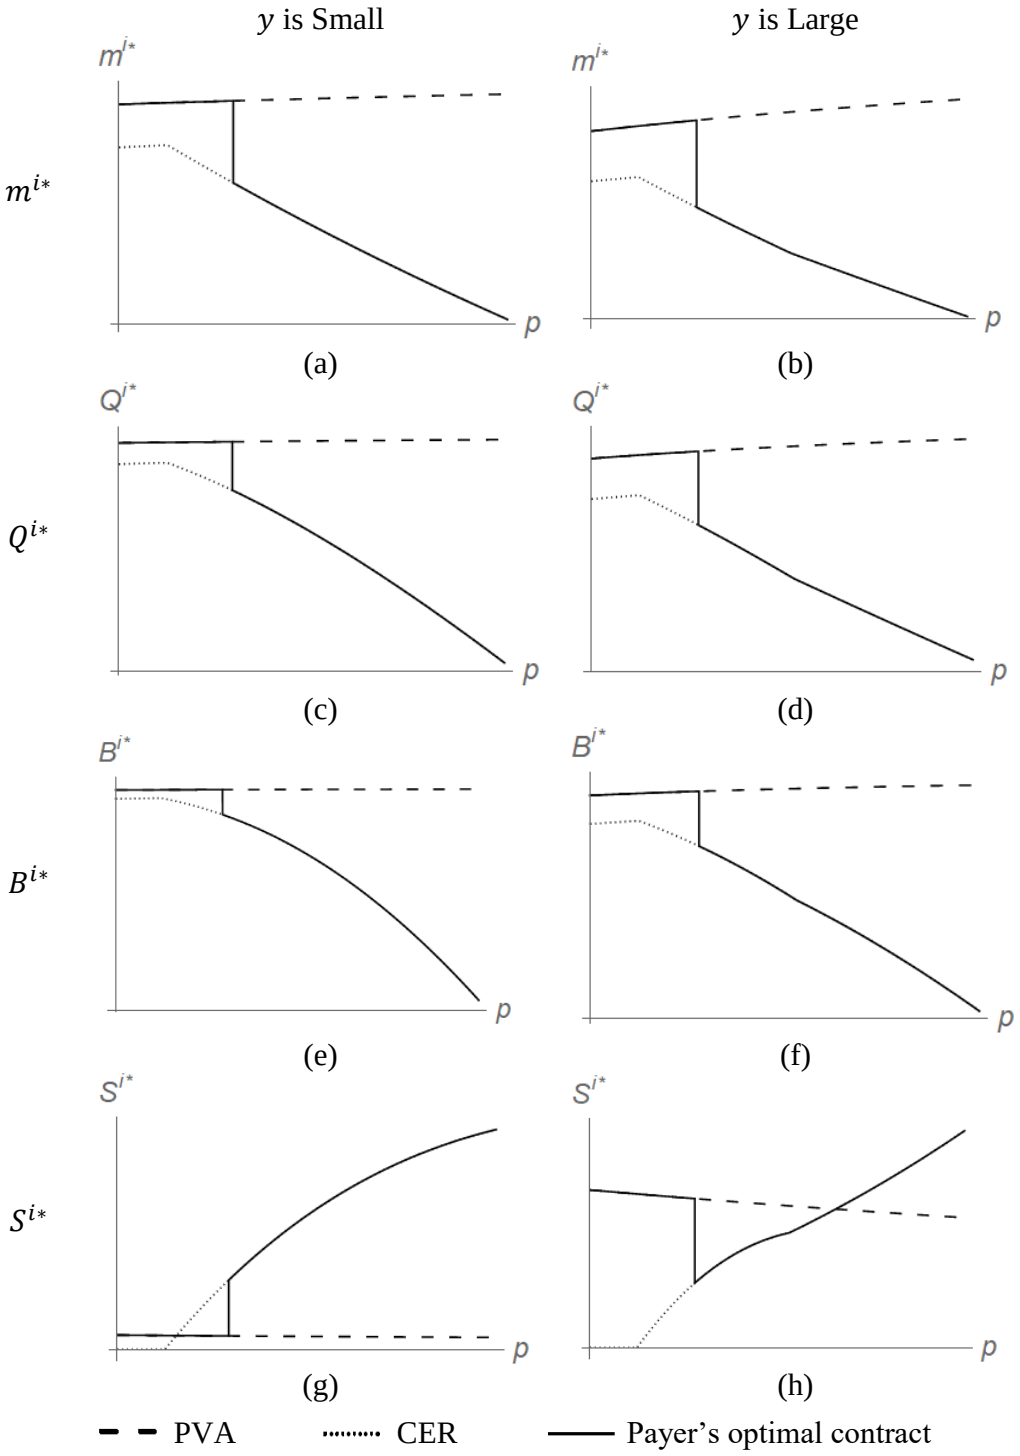


Figure 3 Optimal payoffs when y is small (the lower dashed line in Figure 1) and y is Large (the upper dashed line in Figure 1)

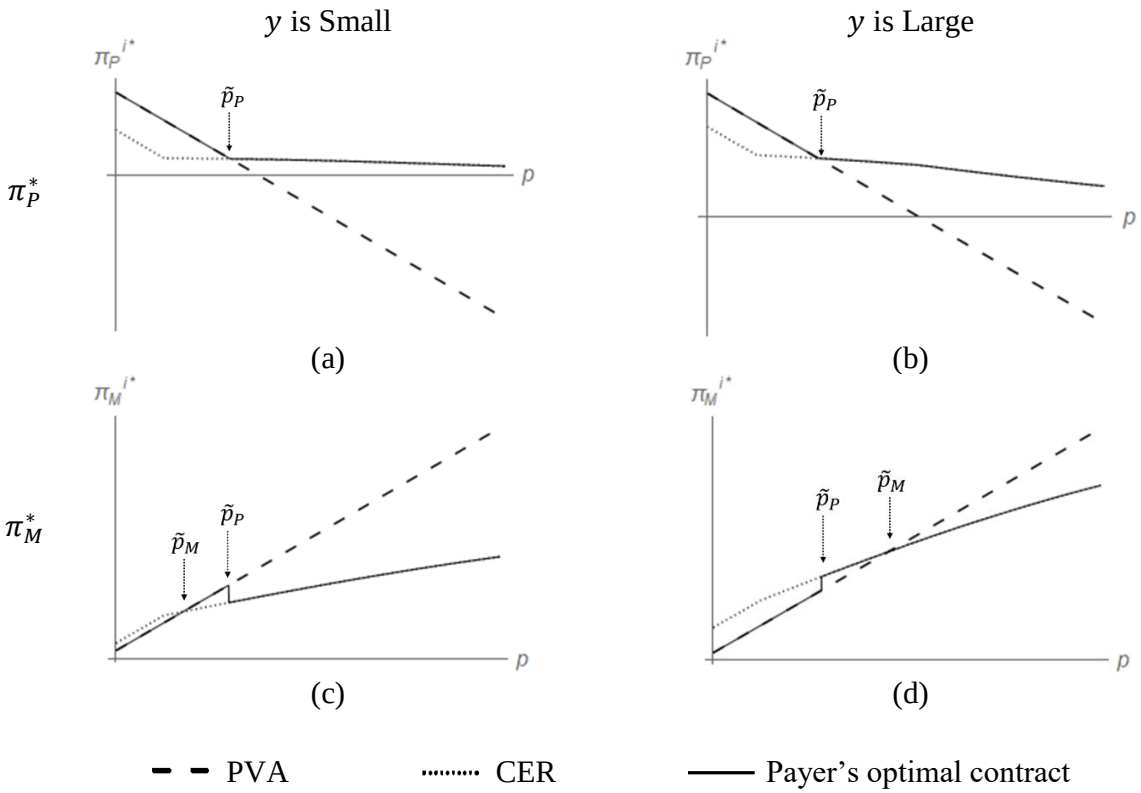

based contract to be preferred by the manufacturer up to a higher price and creates a range for a CER to be preferred by the two parties.

We perform robustness checks on the assumptions made for model tractability. When relaxing the assumption on a bounded uniform distribution and assuming a normal distribution for β and ϵ, the general insights are the same as presented here. If the administration cost is sufficiently high, then there is no region where both parties prefer a PVA, and the general insights for the other three regions remain the same.

CONCLUSION AND DISCUSSION

In this article, we compare the performance of a sales volume-based agreement and a cost-effectiveness-based contract between a payer and a manufacturer as uncertainties in sales volume and cost-effectiveness co-exist in many situations. We find the conditions on when the two parties agree or disagree on the preferred contract. Our study suggests that neither of the two risk-sharing agreements is always preferred by both parties. In general, the payer prefers a PVA but the manufacturer prefers a CER when price is much lower than the payer's willingness to pay. With a sufficiently high drug price, the payer prefers a CER but the manufacturer prefers a PVA. When price is intermediate, the two parties may prefer the same contract depending on the combinations of parameters. For example, both parties may prefer a CER with a broad treatment eligibility and prefer a PVA with a targeted treatment eligibility.

As observed, the two parties may prefer the same contract under certain circumstances. When choosing properly under these circumstances, a risk-sharing agreement can re-distribute risks between the two parties and create an all-win situation: for the payer, both the total health benefit and the cost to the health care system are taken into consideration and maximized; for the manufacturer, market access is accelerated, profit and the resulting incentives for future investment in new drug development are protected; for the patients, as some payer may only list a drug on the formulary with a risk-sharing agreement (Morgan, Thomson, Daw, & Friesen, 2013) due to unforeseeable risks and health budget constraints, such a contract also accelerates patients' access to new drugs and improve patients' welfare.

There are some limitations in this study and future research could consider the following extension directions accordingly. We compared a value-based risk-sharing agreement (a CER) and a volume-based risk-sharing agreement (a PVA) in this model. However, these two types of contracts are not always applicable to both parties. For example, a CER is not an option when outcome is not measurable or there is generic alternative available. Future research could consider other types of risk-sharing agreements to increase options for the two parties such as Patient access schemes (e.g. free drugs, price cap, etc.). We assumed the price is set exogenously, but it could be negotiated between the two parties or a decision variable of either party depending on their power. We assumed all parameters are publicly known and did not consider any information asymmetry. However, some key parameters of the health benefit could be one party's private information. For example, the manufacturer may have better knowledge on the type of the distribution of health benefit through clinical trial, or the payer may have better knowledge on the information though investigation or research. We assumed the sales limit in a PVA is set equal to the expected sales. However, it could take other forms or be either party's decision.

To our knowledge, this study is the first to compare a value-based and a volume-based risk-sharing contract between a payer and a manufacturer. We provide important insights into the conditions which determine when the two parties agree or disagree on whether a value-based or a volume-based contract is more desirable. As pharmaceutical spending keeps increasing, continued research on this topic is necessary for future design, selection and implementation of those contracts.

APPENDIX

Derivation of the optimal solutions

With the assumption of uniform distribution, the total sales and total health benefit are given by $q = 1 - (y - m + \epsilon)$ and $b = \frac{1-(y-m+\epsilon)^2}{2}$.
As uniform distribution has boundaries, there are two cases:
(1): $y - m - \bar{\epsilon} > 0$, i.e., the lowest value for the actual treatment eligibility is positive.
(2): $y - m - \bar{\epsilon} \leq 0$, i.e., the lowest value for the actual treatment eligibility is zero (actual treatment eligibilities with $y - m + \epsilon < 0$ are out of the defined boundary for ϵ and therefore the values for them are zeros).

Case 1 ($y - m - \bar{\epsilon} > 0$, i.e., $m < y - \bar{\epsilon}$):

The expected totals sales and the expected total health benefit are $Q = 1 + m - y$ and $B = \frac{1}{6}(3 - \bar{\epsilon}^2 - 3(y - m)^2)$.

1 - a. PVA:
With the assumption $x = Q$, the rebate occurs when $p(q - x) = -p\epsilon > 0$, i.e., when $\epsilon < 0$.Thus, $S^{PVA} = \int_{-\bar{\epsilon}}^{0} p(q - x)g(\epsilon)\, d\epsilon = \frac{p\bar{\epsilon}}{4}$. The manufacturer's payoff is concave ($\frac{d^2\pi_M^{PVA}}{dm^2} = -2k < 0$). The first derivative of π_M^{PVA} with respect to m is $\frac{d\pi_M^{PVA}}{dm} = p - 2km + c_M$.The first order necessary condition for m^{PVA*} is $\frac{d\pi_M^{PVA}}{dm} = 0$. With the condition for case i, the optimal marketing effort is shown in Table A1. The two parties' optimal payoffs are calculated by plugging in m^{PVA*} and shown in Table A1.

1 - b. CER:
The rebate occurs when $(p + c_P + a_P^{CER})q - \lambda b > 0$, i.e., when $\epsilon \leq \epsilon^{CER} = \frac{2(p+c_P+a_P^{CER})}{\lambda} - 1 + m - y$. We compare ϵ^{CER} with the boundaries of ϵ and obtain three cases:
(a) $\epsilon^{CER} < -\bar{\epsilon}$; (b) $-\bar{\epsilon} \leq \epsilon^{CER} \leq \bar{\epsilon}$; (c) $\epsilon^{CER} > \bar{\epsilon}$.

1 - b - i. $\epsilon^{CER} < -\bar{\epsilon}$
The condition for this case is $m < 1 - \bar{\epsilon} + y + \frac{2(p+c_P+a_P^{CER})}{\lambda}$. The rebate never occurs and thus $S^{CER} = 0$. The optimal values are solved with the same manner and shown in Table A2.

1 - b - ii. $-\bar{\epsilon} \leq \epsilon^{CER} \leq \bar{\epsilon}$
The condition for this case is $1 - \bar{\epsilon} + y + \frac{2(p+c_P+a_P^{CER})}{\lambda} < m < 1 + \bar{\epsilon} + y - \frac{2(p+c_P+a_P^{CER})}{\lambda}$. The expected rebate is $S^{CER} = \int_{-\bar{\epsilon}}^{\epsilon^{CER}} \left(\left(p + c_P + a_P^{CER}\right)q - \lambda b\right) g(\epsilon)\, d\epsilon = \frac{\left(2\left(p+c_P+a_P^{CER}\right)-(1-m-\bar{\epsilon}+y)\lambda\right)^2\left((2+m+\bar{\epsilon}-y)\lambda-\left(p+c_P+a_P^{CER}\right)\right)}{12\bar{\epsilon}\lambda^2}$. The optimal values are solved with the same manner and shown in Table A2.

1 - b - iii. $\epsilon^{CER} > \bar{\epsilon}$

The condition for this case is $m > 1 + \bar{\epsilon} + y - \frac{2(p+c_P+a_P^{CER})}{\lambda}$. The rebate is $S^{CER} = \int_{-\bar{\epsilon}}^{\bar{\epsilon}} \left(\left(p + c_P + a_P^{CER}\right)q - \lambda b\right) g(\epsilon)\, d\epsilon = (p + c_P + a_P^{CER})(1 + m - y) - \frac{1}{6}(3 - \bar{\epsilon}^2 - 3(y - m)^2)\lambda$.
The optimal values are solved with the same manner and shown in Table A2.

Case 2 ($y - m - \bar{\epsilon} \leq 0$, i.e., $m \geq y - \bar{\epsilon}$):

The expected totals sales and the expected total health benefit are given by $Q = 1 - \frac{(y+\bar{\epsilon}-m)^2}{4\bar{\epsilon}}$ and $B = \frac{1}{2} - \frac{(y+\bar{\epsilon}-m)^3}{12\bar{\epsilon}}$ when $y - m + \epsilon > 0$, $Q = 1$ and $B = \frac{1}{2}$ when $y - m + \epsilon \leq 0$.

2 - a. PVA:
The expected rebate is $\frac{p(m+\bar{\epsilon}-y)(y-m+\bar{\epsilon})^2}{8\bar{\epsilon}^2}$ when $y - m + \epsilon \leq 0$, and $\frac{p(y+\bar{\epsilon}-m)^4}{64\,\bar{\epsilon}^3}$ when $y - m + \epsilon > 0$, and the total expected rebate is the sum of the two quantities. The optimal values are solved with the same manner and shown in Table A1.

2 - b. CER:
With similar procedure in other cases, we solve the optimal values and conditions for this case which are shown in Table A2.

ABSTRACT

We study volunteer management at a large faith-based organization that operates a charity storehouse. The whole supply chain works exclusively with volunteers from supply to delivery. We model the preparation of beneficiaries' orders by volunteers in the storehouse as a function of volunteer experience and congestion. We explore how operational decisions, such as the type of volunteers' pairing in teams and whether to allow or impede congestion, affect two performance measures: on-time order preparation rate and additional time to prepare the orders. Using empirical data, we build a simulation model to study these relations.

Who should be served first and who would not be admitted when customers require different service durations?

Sangdo (Sam) Choi
Christopher Newport University
Email: knowhow.schoi@gmail.com

ABSTRACT

The inverse newsvendor model determines the number of customers that could be served in the time available, measured in units of time. For identically distributed service durations, decision variable of interest is the number of assigned (or admitted) customers. For non-identically distributed service durations, we have to determine who to be assigned first and who would not be admitted. We take into accounts both identical and nonidentical normal service durations. We propose three heuristics to decide who to be served when all customers require different service durations, based upon the optimal assigned number of customers when all customers require an identical service duration. We conduct extensive numerical studies to show the efficacy of the heuristics.

KEYWORDS: Inverse Newsvendor, Stochastic Demand, Fixed Capacity, Demand Setting, Customer Admission

INTRODUCTION

The traditional newsvendor problem harkens back to the age-old problem of choosing the number of newspapers to stock in a vending machine in order to achieve a service level under a known stochastic demand distribution that will maximize profit in a single period (Edgeworth 1888, Arrow and Harris 1951). The inverse newsvendor problem is a variant of the traditional approach where the problem is characterized by choosing a demand distribution that could be fit in the available capacity. Industrial applications would be service-oriented firms such as hospital and law-firm. Capacity cannot typically be stored for service organizations. The stochastic element in this paper is the time required to provide service that we refer to as the service duration. In our study, by selecting customers to be served, we implicitly choose the total service duration. That is, the total time to serve all customers is simply the sum of the individual service durations. Since the total service duration represents demand, the decision is tantamount to choosing the demand distribution and this gives rise to the phrase inverse newsvendor model that was first coined by Carr and Lovejoy (2000). Our problem is similar to Carr and Lovejoy (2000), but our focus is on choosing customers to be served rather than explicitly choosing a demand distribution.

There are a few other studies that also address the inverse newsvendor models. Taaffe et al. (2008a) allow a supplier to shape the best demand distribution for a single product by selecting from different potential markets, naming the selective newsvendor problem. Taaffe et al. (2008b) allow for demand flexibility by modeling a random demand as consisting of a set of potential demands. Bakal et al. (2008) address a planning problem to construct a demand portfolio (e.g., market, price, purchase quantity) from a set of potential markets having price-sensitive demands. Taaffe et al. (2008a), Taaffe et al. (2008b), and Bakal et al. (2008) take into

account a set of various parameter values of potential demand distributions. Merzifonluoglu et al. (2012), which is similar to our problem, model a stochastic knapsack assignment, show a Karush-Kuhn-Tucker (KKT) condition for the optimality, and suggest a branch-and-bound approach to select a subset of items with random sizes, which allows nonidentical distributions. All prior studies except Merzifonluoglu et al. (2012) try to select demand distribution itself. Our main approach is to determine the demand size (i.e., discrete opportunity set) assuming that each demand follows independently distributed service duration.
Carr and Lovejoy (2000), Taaffe et al. (2008a), Merzifonluoglu et al. (2012), and Choi and Wilhelm (2014b) assume that demands are independent and normally distributed, while Taaffe et al. (2008b) assumes the Bernoulli distribution, a discrete one. Choi and Wilhelm (2014b) take into account identical service durations in each operating room and allow different normal service durations for multiple operating rooms. We take into account both identically and nonidentically normally distributed service durations, the latter of which can be applied to the static stochastic knapsack problem (Merzifonluoglu et al. 2012).
The remainder of this paper is organized as follows. Section 2 defines the inverse newsvendor model with parameters and decision variables and provides analysis for identically and normally distributed service durations. We prescribe a closed-form solution to the inverse newsvendor model. We prescribe three heuristics based upon the fundamental results. Section 3 provides numerical studies to show various effects of penalty costs. Section 4 concludes our study with future research directions.

MATHEMATICAL MODEL

The decision of interest is to choose $\boldsymbol{x}$ customers to be served in a period with the objective of minimizing the costs associated with a mismatch between the total service duration and available capacity that are both measured in units of time when all customers require the same service durations. Two penalty cost factors are considered. We have 1) penalty cost $\boldsymbol{\ell}$ for under-usage that results in lost sales and 2) penalty cost h for over-usage that corresponds to overtime. Capacity $\boldsymbol{c}$ is fixed, measured in time units, and without loss of generality, we assume that time units are in minutes. For nonidentical service durations, our interest lies in who will be served and who will not be admitted to minimize the sum of expected under- and over-usage. First, consider the identically distributed service durations. Let $\boldsymbol{\Pi}$ denote the random variable representing the service duration in minute for an individual customer. We assume that $\boldsymbol{\Pi}$ has a mean of $\boldsymbol{\mu}$ and variance of $\boldsymbol{\sigma^2}$. Service durations are independent and identical random variables across customers. Hence there is no correlation between two pair-wise individual customer service durations, although this is an important avenue for future research in this area. The total service duration is a random variable defined as $\boldsymbol{\Pi^x}$ with mean $\boldsymbol{x\mu}$ and variance $\boldsymbol{x\sigma^2}$ such that $\boldsymbol{\Pi^{x+y} = \Pi^x + \Pi^y}$. Choi and Ketzenberg (2018) establish how to find the optimal value of $\boldsymbol{x}$, i.e., $\boldsymbol{x^*}$. Consider the $\boldsymbol{x}$-fold sum of the individual normal service duration $\boldsymbol{\Pi}$ with mean $\boldsymbol{\mu}$ and variance $\boldsymbol{\sigma^2}$. The optimal value $\boldsymbol{x^*}$ is expressed explicitly as follow:

$$x^* = \lfloor \hat{x} \rfloor \text{ or } \lceil \hat{x} \rceil \tag{1}$$

$$\text{where } \hat{x} = \left(\frac{-z\sigma + \sqrt{z^2\sigma^2 + 4\mu c}}{2\mu} \right)^2 \tag{2}$$

Now, consider non-identically distributed service durations. Suppose that there are N customers, of which index is $\boldsymbol{i = 1, 2, \ldots, N \in I}$, respectively and that individual service duration $\boldsymbol{\Pi_i}$ of customer $\boldsymbol{i}$ has mean of $\boldsymbol{\mu_i}$ and standard deviation of $\boldsymbol{\sigma_i}$. New decision variable $\boldsymbol{x_i}$ is a binary variable, 1 if customer $\boldsymbol{i}$ is served, 0 otherwise. The number of customers to be served is

$\sum \boldsymbol{x_i}$, which is equivalent to $\boldsymbol{x}^*$for the case of identical normal distributed service durations, i.e., (1) and (2). The total service duration is defined as $\sum \boldsymbol{x_i \Pi_i}$. The inverse newsvendor problem with non-identical service durations can be represented as follows:

$$\min_{x_i} \ell E[(c - \sum x_i \Pi_x)^+] + hE[(\sum x_i \Pi_i - c)^+] \quad (3)$$

We have to evaluate $\boldsymbol{2^N - 1}$ possible combinations to find the optimal number of customers to be served, because we are able to analytically evaluate $\boldsymbol{E}[(\boldsymbol{c} - \sum \boldsymbol{x_i \Pi_x})^+]$ and $\boldsymbol{E}[(\sum \boldsymbol{x_i \Pi_i} - \boldsymbol{c})^+]$ (Choi and Wilhelm 2014a). To find the optimal solution based on numerical evaluation of (3), we reformulate the inverse newsvendor model using Stochastic Programming (SP) with scenarios $\boldsymbol{\omega} \in \boldsymbol{\Omega}$. We adopt the sample average approximation (SAA) approach (Birge and Louveaux 1997) to get a close approximation. Let $\boldsymbol{\Pi_i^\omega}$ be the service duration for customer $\boldsymbol{i}$ under scenario $\boldsymbol{\omega}$; $\boldsymbol{u^\omega}$ under-usage under scenario $\boldsymbol{\omega}$; $\boldsymbol{o^\omega}$ over-usage under scenario $\boldsymbol{\omega}$; $\boldsymbol{p^\omega}$ probability of scenario $\boldsymbol{\omega}$, respectively. SP formulation is given as follows:

$$\min \ell \sum u^\omega p^\omega + h \sum o^\omega p^\omega \quad (4)$$

$$\text{s.t. } \sum x_i \Pi_i^w + u^w \geq c, \omega \in \Omega \quad (5)$$

$$\sum x_i \Pi_i^w - o^w \leq c, \omega \in \Omega \quad (6)$$

Equation (4) defines the objective function; (5) under-usage under scenario ω; (6) over-usage under scenario $\boldsymbol{\omega}$, respectively. We can get the optimal solution based on the SAA approach. However, it is hard to derive a certain (intuitive) rule for the optimal allocation of customers. We suggest three heuristics to get a near-optimal solution in a reasonable time limit: smallest-variance (SV) first, smallest-coefficient-of-variation (SCV) first, and smallest-mean (SM) first selection rules. Such heuristics are based on the discussion that partial expected values are associated with variability rather than central location measure (e.g., mean or median) (Choi and Wilhelm 2012). All three heuristics are the same except the sequencing rule. We conjecture that it is optimal or near-optimal if the number of the assigned customers is equal to the solution to the (1) and (2). In other words, we take advantage of the result from i.i.d. normal service durations, i.e., (1) and (2).

Suppose that $\boldsymbol{n}$ customers are about to be served. Let $\boldsymbol{\bar{\mu}}$ be the sample average service duration for $\boldsymbol{n}$ customers; $\boldsymbol{\bar{\sigma}}$, the standard deviation of sample average service durations for $\boldsymbol{n}$ customers, respectively. If $\boldsymbol{n}$ is equal to the solution of (1) and (2) with $\boldsymbol{\bar{\mu}}$ and $\boldsymbol{\bar{\sigma}}$, we stop adding customers to be served. As $\sum \boldsymbol{x_i}$ increases, the objective function (3) is decreasing-then-increasing. When the current solution $\boldsymbol{x}^*$ is greater than the optimal number of assigned customers, the objective function (3) increases as we assign additional customers. Hence, the stopping rule is valid. We show the detail procedure of the heuristic with the SV selection rule, for example, as follows:

Algorithm for the Heuristic with the SV selection rule

Initialization. Let $\boldsymbol{A} = \boldsymbol{A}^* = \{\}$, $\mathbb{N} = \{\boldsymbol{1, 2, \dots, N}\}$, and $\boldsymbol{Z_{opt}} = \infty$, respectively.

Step 1. Select $\boldsymbol{i}$ with the smallest variance, i.e., $\boldsymbol{i} = \mathbf{arg\,min}\{\boldsymbol{\sigma_k}, \boldsymbol{k} \in \mathbb{N}\}$. Remove $\boldsymbol{i}$ from $\mathbb{N}$ and add $\boldsymbol{i}$ to $\boldsymbol{A}$.

Step 2. Compute sample mean, $\boldsymbol{\bar{\mu}}$ and sample standard deviation, $\boldsymbol{\bar{\sigma}}$ of the set A as follows:

$$\bar{\mu} = \frac{\sum_{k\in\mathbb{N}} \mu_k}{|\mathbb{N}|}$$

$$\bar{\sigma} = \sqrt{\frac{\sum_{k\in\mathbb{N}} \sigma_k^2}{|\mathbb{N}|}}$$

Step 3. Plug $\bar{\boldsymbol{\mu}}$ and $\bar{\boldsymbol{\sigma}}$ into (1) and (2) to compute $\boldsymbol{x}^*$.
Step 4. Compute the objective function value $\boldsymbol{Z_{curr}} = \boldsymbol{\ell E}[(\boldsymbol{c} - \sum \boldsymbol{x_i \Pi_x})^+] + \boldsymbol{hE}[(\sum \boldsymbol{x_i \Pi_i} - \boldsymbol{c})^+]$ (Choi and Wilhelm 2014a). If $\boldsymbol{Z_{curr}} < \boldsymbol{Z_{opt}}$, let $\boldsymbol{A}^* \leftarrow$ A and $\boldsymbol{Z_{opt}} \leftarrow \boldsymbol{Z_{curr}}$.
Step 5.If $\boldsymbol{x}^* \leq |\boldsymbol{A}^*|$ and $\mathbb{N} \neq \{\}$, go to Step1. Otherwise, go to Step 6.
Step 6. Let $\boldsymbol{A}^*$ be the set of optimally assigned customers and $\boldsymbol{Z_{opt}}$ be the heuristic result.

For the SM and SCV heuristics, we modify the Step 1 with an appropriate sequencing rule. The SM heuristic selects $\boldsymbol{i} = \mathbf{arg\,min}\{\boldsymbol{\mu_k}, \boldsymbol{k} \in \mathbb{N}\}$; the SCV $\boldsymbol{i} = \mathbf{arg\,min}\{\boldsymbol{CV_k}, \boldsymbol{k} \in \mathbb{N}\}$, respectively. We show how the SV heuristic works for next simple example. We use the cost ratio of 0.5:0.5; 120 minutes blocks without loss of generality. Table 1 shows all parameter values of twelve customers: μ, σ, and CV, respectively. Note that the expected required service duration for all twelve customers (i.e., 263.8 minutes) is much larger than the given capacity, 120 minutes.

Table 1: Parameter values for $\boldsymbol{\mu, \sigma,}$ and CV of twelve customers. Parameter values have been generated randomly.

Index(i)	1	2	3	4	5	6	7	8	9	10	11	12
$\boldsymbol{\mu_i}$	18.5	24.0	27.9	24.9	28.5	26.8	27.5	16.7	27.3	19.8	11.6	10.3
$\boldsymbol{\sigma_i}$	6.5	11.6	21.7	17.3	7.5	18.8	5.7	10.4	3.9	6.4	5.6	1.8
$\boldsymbol{CV_i}$	0.35	0.48	0.78	0.69	0.26	0.70	0.21	0.62	0.14	0.32	0.48	0.17

The SV heuristic will select customers as the following order: 12 → 9 → 11 → 7 → 10 → 1 → · · · → 3; the SCV heuristic, 9 → 12 → 7 → 5 → 10 → 1 → · · · → 3; the SM heuristic, 12 → 11 → 8 → 1 → 10 → 2 → ⋯ → 5, respectively. The followings are detail steps resulted from the SV selection rule.

Iteration 7

$\boldsymbol{A}$ = {12,9,11,7,10,1,5}; $\bar{\boldsymbol{\mu}}$= 20.51; $\bar{\boldsymbol{\sigma}}$= 5.64; $\boldsymbol{x}^*$= 6 < $|\boldsymbol{A}^*|$ = 7; $\boldsymbol{Z_{curr}}$ = 12.15; $\boldsymbol{Z_{opt}}$= 5.53; $\boldsymbol{A}^*$ ={12,9,11,7,10,1}.Stop.

NUMERICAL STUDY

We conduct extensive numerical studies to evaluate the efficacy of three heuristics by comparing them with the optimal allocation resulted from the SAA approach. We take into account cost ratio, $\boldsymbol{\mu_i}$, and $\boldsymbol{\sigma_i}$ (equivalently $\boldsymbol{CV_i}$). Capacity, c is 240 or 480 minutes without loss of generality. μi and c are scaleable. We find little difference between the case of c = 240 and the case of c = 480. Hence, we show the case of c = 480 minutes in Table 2. We generate N = 25 customers with mean times $\boldsymbol{\mu_i}$, generated from U[10, 25]; $\boldsymbol{CV_i}$ from U[0.1, 0.7], respectively. We exclude the case of $\boldsymbol{CV_i}$ ≥ 0.7, because it is less likely for them to be selected owing to the effectiveness of the SV or SCV rule. We use five cost ratios, h:l = 0.1:0.9, 0.3:0.7, 0.5:0.5, 0.7:0.3, and 0.9:0.1 to see how cost ratios affect the allocation decision. For each cost ratio combination, we run ten simulations. We assign simulation index to each scenario, from 1 to 50. Preliminary tests show that we have little variance when we generate around 1,000 scenarios. For the sake of robustness, we test 10,000 scenarios in order to reduce an optimality gap to a minimum.

Table 2: A comparison of optimal allocation and three heuristics: SM, SCV, and SM. For each cost ratio combination, the first five results are shown.

Simulation Index	$\boldsymbol{c^w}$: $\boldsymbol{c^i}$	GAP			SCV			
		SV	SCV	SM	Opt	SV	SCV	SM

45		1	6	60	10	10	10	12

Table 2 describes a comparison of three heuristics and the optimal allocation and Table 3 shows a summarized result of the pairwise matched t-test. The first column from the left of Table 2 is simulation index; the second one, cost ratio; the third through the fifth one, gap values between optimal and each heuristic; the sixth through ninth one, the number of customers to be served resulted from the optimal and three heuristics, respectively. We do not show all 50 simulation results, but the first five results of each cost ratio combination. Hence, simulation indices shown in Table 2 are 1 through 5; 11 through 15; 21 through 25; 31 through 35; 41 through 45, respectively. In addition, we conduct the matched t-test to verify our findings, as shown in Table 3, which provides p-value for each matched two-tailed t-test when $\boldsymbol{c}$ = 240 minutes. We compare the objective values as well as the number of assigned customers. The first column of Table 3 is the cost ratio combination; the second mean value; the others p-value for each pairwise t-test. The first row of each cost combination is about the comparison of the objective values; the second row the comparison of the assigned customers, respectively. The null hypothesis is as follows:

$$H0 : Opt \equiv SV \equiv SCV \equiv SM.$$

Cost ratio affects without respect to the selection rules. When $\boldsymbol{c^i} > \boldsymbol{c^w}$, it tends to assign more customers in order to avoid under-usage penalties more than over-usage penalties. On the contrary, it tends to assign fewer customers to avoid over-usage penalties more than under-usage penalties when $\boldsymbol{c^i} < \boldsymbol{c^w}$.

Table 3: p-value for matched two-tailed t-test. We use **bold** face for the p-value of 0.01 or greater in order for readers to easily contrast it with $\boldsymbol{\alpha}$. Vey small p-vlaue's (e.g., 0.00001) are expressed as <0.0001.

$\boldsymbol{c^w}$: $\boldsymbol{c^i}$	Mean value	Opt vs. SV	Opt vs. SCV	Opt vs. SM	SV vs. SCV	SV vs. SM	SCV vs. SM
0.1:0.9	Obj value	**0.0301**	0.0013	<0.0001	**0.2635**	<0.0001	0.0002
	Customers	**0.0150**	0.0031	<0.0001	0.0002	0.0002	<0.0001
0.3:0.7	Obj value	**0.0116**	0.0017	<0.0001	**0.6786**	<0.0001	<0.0001
	Customers	**0.0522**	0.0007	0.0007	0.0001	0.0002	<0.0001
0.5:0.5	Obj value	**0.0523**	0.0059	<0.0001	**0.2789**	0.0001	<0.0001
	Customers	**0.0248**	**0.0239**	<0.0001	0.0007	0.0003	<0.0001
0.7:0.3	Obj value	0.0032	0.0029	<0.0001	**0.9213**	<0.0001	<0.0001
	Customers	**0.0107**	0.0002	0.0005	0.0002	**0.0107**	<0.0001
0.9:0.1	Obj value	**0.0160**	**0.0103**	<0.0001	**0.2789**	<0.0001	<0.0001
	Customers	0.0007	**0.0368**	<0.0001	0.0002	0.0007	<0.0001

Most p-value's (the first row) for the matched t-test against the null hypothesis of Opt ≡ SV are boundary at the significance level of α = 0.5 or 0.1. Technically, we fail to reject the null hypothesis, depending upon the significance level α. The SV heuristic provides a close objective function value to the optimal, and the gap between the optimal allocation and the SV heuristic can be regarded as marginal, i.e., 4% on average. We obviously fail to reject the null hypothesis of SV ≡ SCV because of high p-value, e.g., greater than 0.25. The SV heuristic and the SCV heuristic give close but slightly different objective values. The objective function value gap between the SV heuristic and the SCV heuristic is 3% because the gap between the optimal allocation and the SCV is 7%. However, the SV heuristic slightly outperforms the SCV heuristic,

32 times out of 50 simulations. Both the SV and the SCV heuristics outperform the SM heuristic and p-value's are so small to reject the null hypotheses of SV ≡ SM and SCV ≡ SM, respectively. The gap between the optimal allocation and the SM heuristic is 39%. Note that both $\boldsymbol{E}[(\boldsymbol{c}-\boldsymbol{\Pi}^{\boldsymbol{x}})^{+}]$ and $\boldsymbol{E}[(\boldsymbol{\Pi}^{\boldsymbol{x}}-\boldsymbol{c})^{+}]$ are related to the deviation from the given capacity $\boldsymbol{c}$ (Choi and Wilhelm 2012), or variability measure rather than location measure (e.g., mean or median). p-value's (the second row) greater than α for the null hypothesis of Opt ≡ SV show that the assigned numbers between them are little different. p-value's smaller than α for the null hypothesis of SV ≡ SCV show that the assigned numbers between them are significantly different. p-value's with respect to the objective function value and the assigned number conclude that the SV and SCV heuristics assign a different number of customers but their objective function values are close. The SM heuristic assigns one more customer and has the worst gap among three rules, because the SM rule has nothing to do with variability measure (e.g., $\boldsymbol{E}[(\boldsymbol{c}-\boldsymbol{\Pi}^{\boldsymbol{x}})^{+}]$, $\boldsymbol{E}[(\boldsymbol{\Pi}^{\boldsymbol{x}}-\boldsymbol{c})^{+}]$) directly.
Hence, the SM heuristic is the worst among three heuristics. The SV and the SCV heuristics are closely related in terms of variability. Variance is a direct measure of variability and the SCV heuristic takes into account the only variability, whereas CV is a relative measure of variability, i.e., $\boldsymbol{c}$. Smaller CV means either smaller variance, or larger mean, or both. Hence, the SCV heuristic $\boldsymbol{\mu}$ tends to assign fewer customers than other heuristics for some combinations.
We recommend that one use the SV heuristic first and compare it to the SCV heuristic later, because the SV heuristic outperforms the SCV heuristic slightly, gap between optimal and the SV heuristic is smaller than gap between the optimal and the SCV heuristic, and the SV heuristic provides optimal result 15 times out of 50 simulations; the SCV, 8 times of 50, respectively.

CONCLUSION

We investigate the inverse newsvendor model with normal distributed service durations. We prescribe three heuristics for nonidentically normally distributed service durations, based upon the results from identical normal service durations. With these heuristics, one may decide how many will be served, who will be served first, and who would not be admitted in a capacitated environment.
There might be several avenues for future research. A notable example is extending the problem to multi-period problems. This would correspond to situations in which the current period decisions affect the future period decisions, as might occur when certain specialized labor is restricted to the case when they cannot work more than a certain number of hours in a month. Choi and Banerjee (2015) studied a multi-period inverse newsvendor model with identical normal service durations. One can combine our approach and Choi and Banerjee (2015) for multi-period newsvendor model with non-identical normal service durations Other research could address some of our limiting assumptions. For example, we assume that penalties are the same across customers, but this need not be the case. Each customer may have different weight of importance. In this case, the order of customers served may become an important decision particularly if the penalties for earliness or lateness vary by customer. Lastly, different service durations can be taken into account. Note that Choi and Wilhelm (2012) studied normal, gamma, and lognormal service durations with one patient in one block.

ABSTRACT

Visualizing and analyzing large spatial-temporal movement data can be tedious and time-consuming. We have designed and developed WIGA, a web-based application for managing, visualizing and analyzing movement data by integrating an open source graph database and visual analytics methodology. In this paper, we share our experience of developing the application as well as the various capability such as transforming large volumes of movement data into well-structured graph database, enabling data analyst to explore and detect the spatio-temporal patterns of these massive movement data with easy to understand visualization.

KEYWORDS: Big movement data, Visual analytics, Graph database, Graph analytics, Visualization, Analyzing, Spatial-temporal data

INTRODUCTION

Movement data provide information about the number of people in a location at a particular point in time. The data also provides insights into movements between two locations. Traditionally, these data were collected through traffic survey which were very time consuming and laborious, not to mention the sample size were relatively small due to financial constraint. The advances in location-based data collection technologies such as GPS, RFID and Internet of Things (IoT) and the rapid reduction of their costs provide us with a huge and continuously increasing amount of data about movement of vehicles, people and goods in and around an area. This huge amount of data not only records the historical activities but also provides valuable information for planners and decision-makers. These massive movement data collected by various devices today contain structure and patterns such as peak times, lull periods that provide useful information to various stakeholders such as street traffic planners, building space planners etc. The identification, analysis and comparison of such patterns captured through vehicle movements will provide further insights into human movement and behaviors within a city or a region. These understandings will potentially contribute to a better transport management and useful information to both private and public transport services providers to formulate informed decision to gain competitive advantage on providing timely and quality service. Second use case is social media where users operate in

small sub-networks to large networks and data is generated at a tremendous speed every second. Using similar techniques as demonstrated in this paper social media scientists can analyze the use networks for influencers, interaction patterns, information flows, bottlenecks, user clusters and profiling. Third use case, which we see, is in banks, investment firms and startups where individuals and startups are constantly looking out for venture capitalists (or VCs). Venture capitalists invest in different projects via certain agencies facilitating the investments. A network analysis of this sort can highlight the cluster of these VCs who invest in similar projects and how to connect to a particular VC in a network.

There are myriad applications that emerge out of network and sensor based datasets but the true values of these data will not be fully appreciated until they are processed, analyzed and the analysis results are communicated to decision makers in a user-friendly manner.

The aim of this work is to create a framework that can help to visualize any sensor tracked movement dataset easier. The whole data to visualization pipeline is broken down into smaller chunks that need attention and this paper is an attempt to make it easier for the readers to understand the whole process.

This paper reports on our research and development effort to design and implement a web-enabled visual analytics application for supporting the management, visualization and analysis needs of urban and transport planning professional. It consists of five sections. Section 1 provides a general introduction of the paper. Followed by literature review, an overview of the motivation and objectives of our research effort. Section 3 provides a high-level view of the overall design of WIGA. This is followed by a detailed discussion of the data preparation process. In this section, the graph database design and implementation will be discussed too. In section 5, the data visualization techniques used to design and implement the graphical user- interface (GUI_ of WIGA will be presented. In the next section, the practical use of the WIGA is demonstrated using a set of movement data. Lastly, the paper concludes by highlighting the future direction of the research.

LITERATURE REVIEW

In recent years, big movement data has been one of the major research focus in the academic research community especially in the field of computer science and the software vendors who provide big data services. Dynamic graphs are capturing interests of researchers and industry alike as with growing populations these graphs are emerging everywhere such as computer networks, traffic, social circles etc. These graphs in real life scenarios are quite large and need to be represented and analyzed carefully [10] as they are directed in nature with a considerable number of nodes and their interactions. These works either focus on techniques for massive graph visualization [4] [5] [6], or different ways of looking at the information embedded in graphs [7] [8]. Largely, the current academic research and practice development efforts, however, tend to focus on the technological aspect of big data. To address this need research work has been done [9] but the focus is still theoretical and not on an end-to-end commercially viable product. Such a gap is evident and this paper aims to explore the possible approach to design and implement a *scalable, flexible* big data analytics application by integrating an open source big data processing framework and an open source data visualization analysis environment.

Our research and development efforts were motivated by the general lack of effective and easy to use web-enabled interactive visual analytics tool for discovering spatio-temporal patterns in massive movement data. It aims to provide transport planners and transport services operator with an analytical tool for visual discovery of human movement in a geographical area and their interaction in time and space. Specifically, it attempts to support the following analysis requirements:

1. To manage and transform a large movement data collected from automatic sensor such as RFID and traffic sensors into intelligence graph database;
2. To create an interactive visual analytics framework to display massive movement data over time;
3. To provide a graph visualization and analysis framework that can display the distribution of movement data over time and space; and
4. To be able to display detailed records on-demand.

WIGA-AN OVERVIEW

The development and implementation of WIGA consists of three major phases as shown in the Figure 1 below. They are: (1) Data Processing, (2) Graph Database Design and Implementation, and (3) Visual Analytics Application Design and Development. In the next three sections, a detailed discussion of each of these processes will be shared.

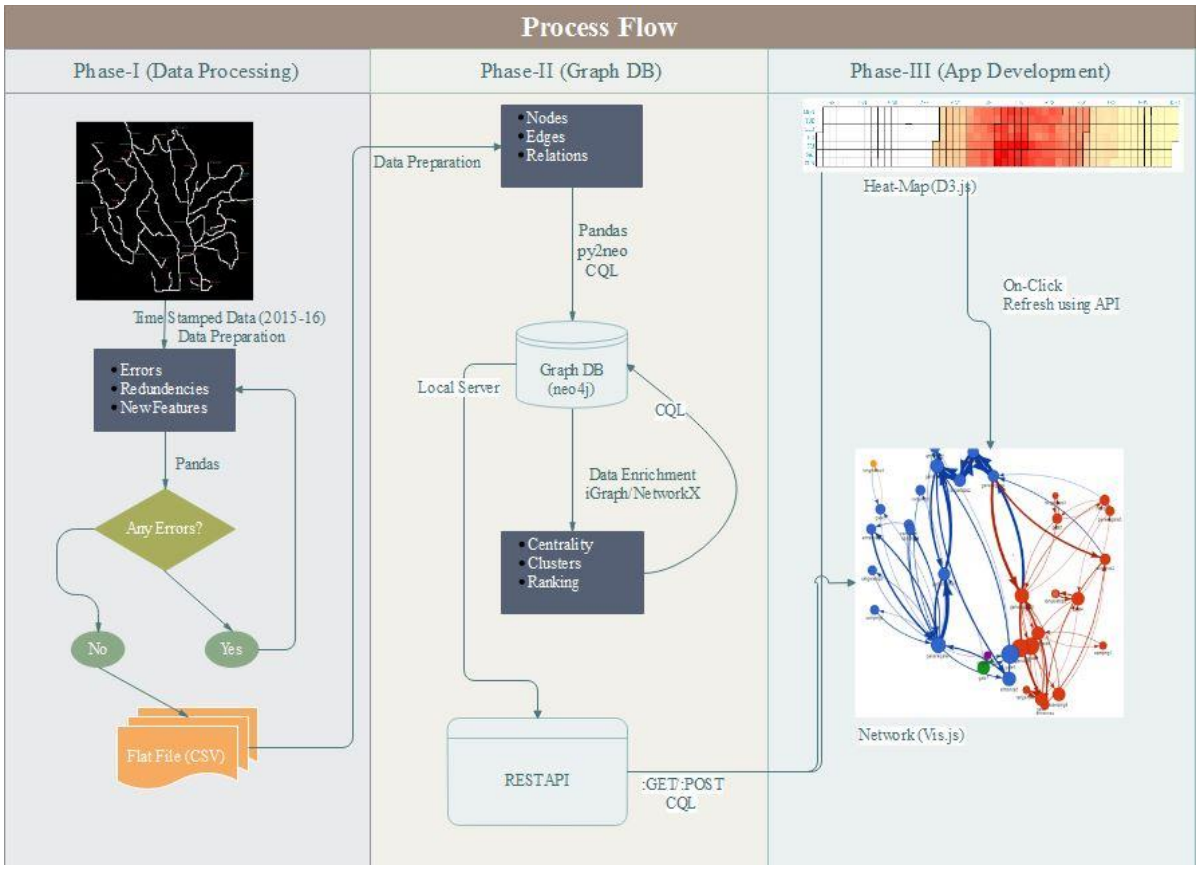

Fig. 1. Design and implementation of WIGA.

PHASE I: DATA PREPARATION AND PROCESSING

The data used for this work comes from VAST 2017 MC-1 [3], which contains a csv file containing data recorded from sensors around the Boonsong Lekagul Nature Preserve. This data set has various merits to for this project:

1. Raw and dirty: many corrections such as duplicate removal, erroneous values corrections were required to make the provided dataset useable for the end-system.
2. Feature Engineering: only four columns were present initially but to unlock the potential patterns we ended up creating 21 columns. A very useful illustration of importance of feature engineering in any data science project.
3. Potential for machine learning: The prepared data can be used for predicting traffic peaks for a given day of week (or year) for a given period. Although it is not the focus of this paper.
   The csv file had 171477 rows and 4 columns as shared below:

TABLE I. THE RAW DATA

Timestamp	car-id	car-type	gate-name
1/5/2015 0:43	20154301124328-262	4	entrance3
1/5/2015 1:03	20154301124328-262	4	general-gate1
1/5/2015 1:06	20154301124328-262	4	ranger-stop2
1/5/2015 1:09	20154301124328-262	4	ranger-stop0
1/5/2015 1:12	20154301124328-262	4	general-gate2
1/5/2015 1:24	20154301124328-262	4	general-gate5
1/5/2015 1:31	20153101013141-937	1	entrance3
1/5/2015 1:33	20154301124328-262	4	entrance4

Initial phase-I of data preparation is focused on identifying data entry errors, deduplication, and creation of new features including digitization of jpg image provided to get location coordinates which can serve as a proxy of latitude and longitude.

For deduplication, a composite key is used which includes all 4 columns ('timestamp', 'car-id', 'car-type', 'gate-name') of the given dataset and duplicate records are first flagged and later excluded from the dataset after careful examination.

As a vehicle moves, from one location (gate) to another (gate) location, using appropriate grouping on car-ids four new columns are created namely EntryGate, EntryTime, ExitGate, and ExitTime. The entry and exit time related columns help further create a set of columns depicting seconds, minutes and days spent between two consecutive time stamps. Similarly, date, day of week, hour of day and year fields were created.

The provided map image of the nature park is used to get the X, Y coordinates of each sensor point. Later, this information is combined with the entry and exit time information between two sensor locations to compute the speed with which a certain vehicle moves between these two locations to observe the violations of speed limits.

All the records where the timestamps between two consecutive locations are the same but the exit gate is different from entry gate, are flagged as erroneous records and are removed consecutively because it is physically impossible for a car to be at different gates at the same time. The final dataset contains 169050 rows and 21 columns. A little redundancy is observed in the dataset to facilitate faster realization of visualizations by avoiding computations on the fly wherever possible.

PHASE II: GRAPH DATABASE DESIGN AND IMPLEMENTATION

The popular avenue to store data these days are, namely, flat files (such as csv), relational databases (such as MySQL) and NoSQL databases (such as MongoDB, Neo4J). For this project, we used a graph database to manage, transform and analysis the movement data. Graph databases fall in the category of NoSQL databases and are suitable for storing, managing and processing large movement data involving large number of connections between entities.

In a graph database, each node (entity or attribute) in the graph database model directly and physically contains a list of relationship-records that represent its relationships to other nodes. These relationship records are organized by type and direction and may hold additional attributes. Whenever you run the equivalent of a JOIN operation, the database just uses this list and has direct access to the connected nodes, eliminating the need for an expensive search/match computation. [11]

For the purpose of our project, Neo4j has been selected to implement the graph database. Neo4J is a JVM application. The reason of using Neo4j to implement our application is because it is known to be a highly scalable native graph database that leverages data relationships and can handle graphs of several billion nodes/relationships/properties on a single machine and also traverse depths of 1000 levels and beyond at millisecond speed.

The dataset after initial phase is still in a csv file and not suitable for graph database hence the phase-II focuses on loading the dataset into a locally run instance of Neo4J database. To load the dataset from initial phase into neo4j, we make use of Cypher Query Language (CQL) of Neo4j and py2neo module of python programming language.

There are two different query languages that can be used to access data in Neo4j, they are: CQL and Gremlin.

In our work, CQL is used to access data stored in Neo4j instance running locally on our computer. Cypher is a declarative, pattern-matching query language that makes graph database management systems understandable and workable for any database user—even the less technical ones.

Using py2neo we incrementally create cypher queries for every car-id with merging similar gate names to keep them unique in the final network. Every time a car moves between two gates, a directed edge with weight one unit is added to the network with few other edge properties such as timestamp, date etc. Peculiar cases happened when a car loops back to same gate, the source and target gates are same with different timestamps, create too many self-loops during the initial data load. Such self-looping inflates the centrality measures and is corrected in subsequent data load refresh. Each car-id will have a node labelled year as a parent to facilitate filtering of data, if needed, on yearly basis while constructing queries.

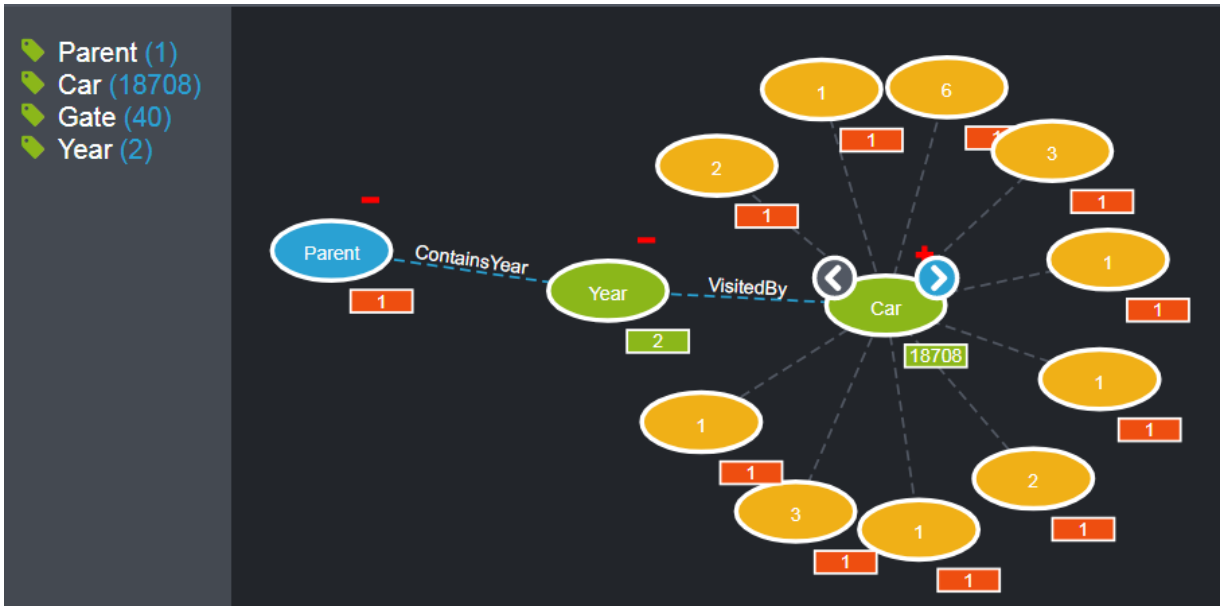

Fig. 2. Hierarchy of Nodes (depicted using popoto.js [12]).

The year node has two distinct values 2015, 2016 and the car node has 18708 distinct cars which further enter a network of 40 gates of the nature preserve. In our work, the focus is on the gate network to study the traffic and usage of these gates at various instance of time. In the network below, one may observe that cars generally start their journeys at one the six gates out of the available 40 gates in the nature preserve.

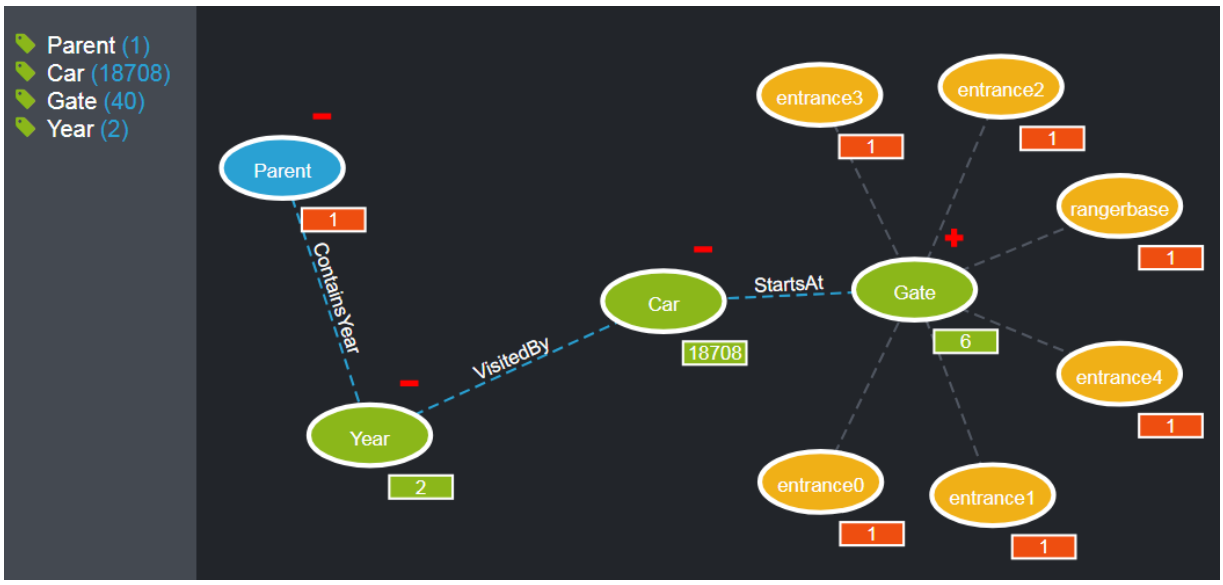

Fig. 3. Car generally starts journey at one of the six gates out of 40 gates. This shows that the park can be visited by only six gates.

Once the dataset gets loaded into the graph database with various pieces of information residing in nodes, edges and their properties, it becomes easy to get various statistics about the network with simple cypher queries.

For example, if we are looking for number of total directed edges in the network:

```
### number of total edges in netwrok
query = """MATCH (c)-[r]->() RETURN count(r)"""
result = graph.cypher.execute(query)
df = pd.DataFrame(result.records, columns=result.columns)
df
```

	count(r)
0	175684

Similarly, it is very easy to compute shortest paths, network diameter, isolated nodes, and in-degrees, out-degrees of all the nodes (gates) for the complete dataset or at any point in time if we wish to analyze the network in between two time periods. All these directly link to some business use cases such as urban planning where commuters can be guided to the locations or priority traffic movements for VIPs. Another example could be connecting isolated locations with a bus route for ensuring accessibility.

The data stored in the graph database is further enriched using python iGraph module to assign values to every node on the centrality measures such as closeness, PageRank, betweenness, cluster (community). We observe that the whole dataset is divided into five clusters using the walktrap algorithm for community detection [13]. PageRank of gates in a park can be used to predict how many vehicles will pass through them. Betweenness can used to find the controlling

gates between two clusters of nodes. The gates can be further monitored to study traffic flow patterns or rate of interaction between two sub-networks identified by clusters.

PHASE III: VISUAL ANALYTICS APPLICATION DESIGN AND DEVELOPMENT

In the final phase, phase-III, we move our focus on providing users with a visual analytics dashboard where they can interact with the graph data stored in Neo4j database and explore the movement data spatio-temporally.

The architecture of WIGA was designed and developed with a purpose to make it an open, flexible and re-usable tool which could be used for analysis and exploration of movement data. As a result of this endeavor, it was decided to make it as a web based tool to enable a wider access by the end users.

The system architecture of WIGA consists of two major views namely: Multi-day Analysis view and Daily Analysis view as shown in the Figure 4. Multi-day is a macro view which serves to explain demand and supply over a period of time for capacity planning. Daily view on the other hand is a micro view, which is more for day to day operations.

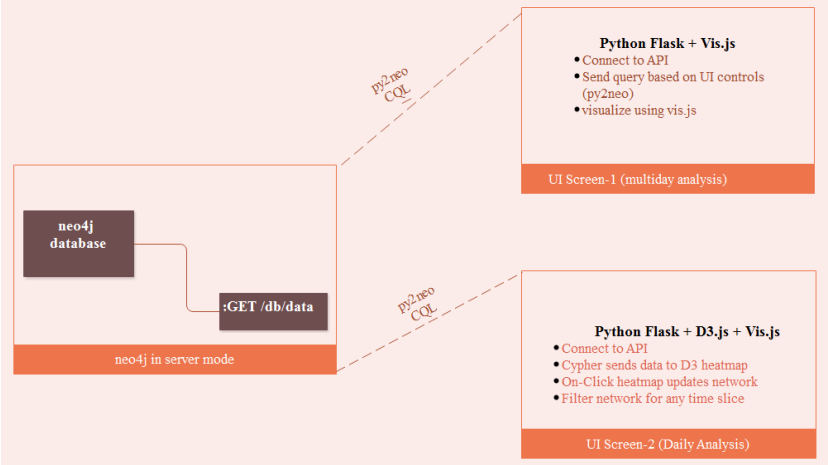

Fig. 4. The Daily Analysis View.

A. The Multi-day Analysis View

The Multi-day view is designed to enable user to analyse the flow patterns of the movement data beyond a single day. As a result, only the graph visualization is provided.

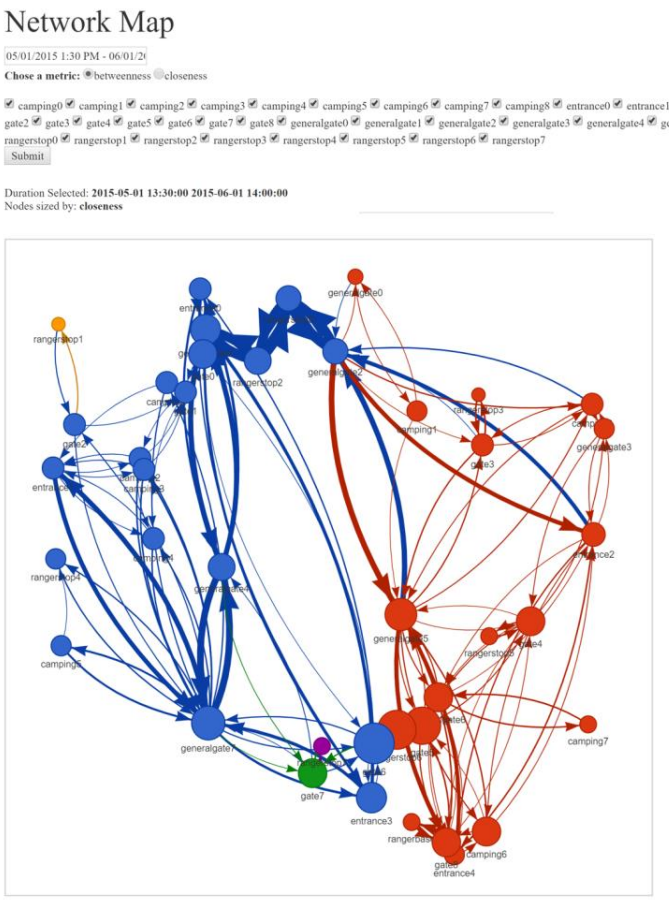

Fig. 5. The Multi-day Analysis View

One of the new interface added in the Multi-day view is the Time Window selector [16]. It is specially used to enable user to select a starting date and time and an end date and time available based on start and end date of dataset.

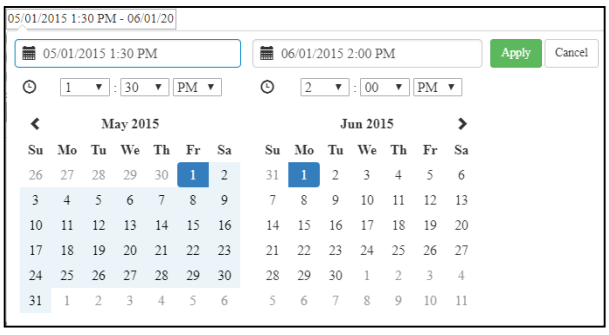

Fig. 6. The time window selector

Besides the Time Window selector, the Multi-day Analysis view also include user-interface to modify the properties of the graph entities such as size of edge, size of node, font of node, just to name a few of them. These user interface provides the user the flexibility to customize their graph visualization.

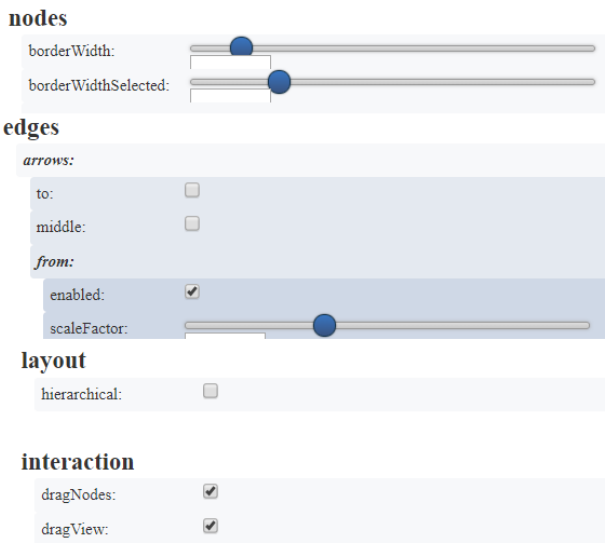

Fig. 7. The graph properties interface.

B. The Daily Analysis View

The Daily Analysis view consists of two data visualization, namely: calendar heatmap [14], a graph visualization and a time selector [8] as shown in the Figure 8 below.

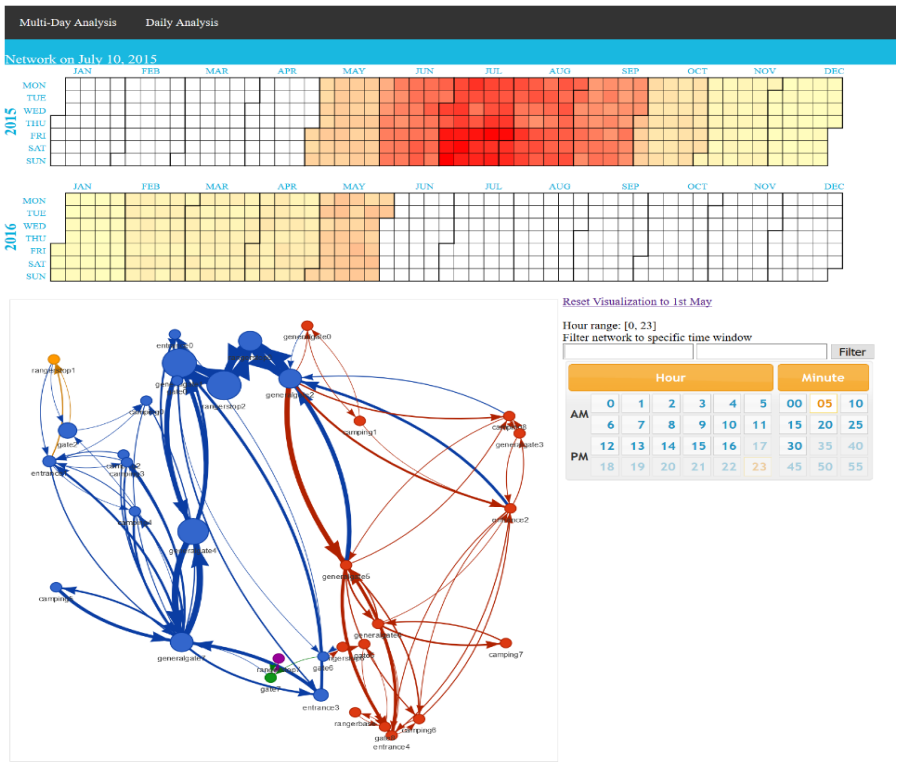

Fig. 8. The Daily Analysis View.

The design of WIGA's visual analytics application follows closely the data visualization general guidelines suggested by Schneiderman's mantra [1]: over, zoom and filter, details on demand. The calendar heatmap is designed to provide an overview of the entire year movement data by day of the week and by month of the year. The network graph visualization reveal detail movement patterns at each entrance, gate and campsite. Lastly, the time selector allows users to select a particular time interval of interest for further detail investigation.

The calendar heatmap is designed using D3.js, a JavaScript library for producing dynamic, interactive data visualizations in web browsers. The calendar heatmap is designed to provide a macro view of the movement data by day of a week, month and year. For example, the calendar heat map above shows using the color intensity (from yellow to red) how the traffic was for every date of month. In the cells dense red color cells represent high number of people on the park.

The graph visualization, on the other hand, is designed using Vis.js, a dynamic, browser based visualization library. It is able to handle large amounts of dynamic data, and to enable manipulation of and interaction with the data.

Although the geo-layout in our work retains the actual locational context and relationships of the entrances, gates and campsites. The edges are used to represent the number of flow from a location to another location. Arrows are used to show the flow direction. The nodes are colored using cluster values. The size of the node are used to represent a centrality measure such as in-degree, out-degree, closeness or betweenness. By default, betweenness values are used to represent the size of the node. We can clearly see separate clusters in the visualization, which are indicative of two sub-networks emerging in the park. Perhaps traffic from different gates stays focused to certain parts of the park.

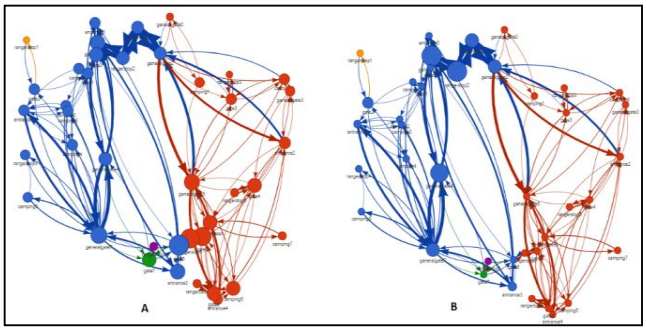

Fig. 9. Nodes sized by closeness (A) and betweenness(B).

To support interactive exploration of the movement data over time and space, coordinated link function has been implemented between the calendar heatmap and graph visualization. This design enables user to click on any grid cell of the calendar heatmap and the graph will reveal the flow patterns occurred on the selected day.

The Time Selector interface, on the other hand, is specially used to support detail investigation of the flow patterns at a selected range of time interval.

CONCLUSION

Although the presented use case is for a sensor-based data monitoring; this work is equally extendible to social media analysis and commercial network analysis for startups. All these uses cases of security, traffic control and optimization, social media analytics and commercial banking and VC networks have similarities of sub-graphs, centrality that generate influencer nodes, bottlenecks. Such analysis also highlights untapped opportunities in a network at large.

The above presentation had provided an indepth discussion of the design and implementation of WIGA. Our initial use of WIGA to analyse movement data provided by Boonsong Lekagul Nature Preserve revealed many interesting patterns.

There are a number of options available for constructing the data pipelines for a visualization but not all are equally flexible. In this context we played by our strengths and picked up technologies such as python flask, d3.js which we were already familiar from past experiences. The graph database Neo4j and the network visualization library Vis.js were new to the team. The team quickly picked up the nuts and bolts of the graph database but mastering the cypher query language took time because the need was not just to fire queries but also to envision and later construct the data model in Neo4j using the cyphers trough python programming language.

The D3.js network visualization is not as configurable as options available with vis.js so we opted for the latter. We used it for both daily and multi-day analysis data pipelines. We linked queries to user inputs to fire them dynamically with ease. Another challenge was to link the heatmaps with the network visualization for daily network chart which was achieved using flask web framework. We further improved this visualization by providing a time slicing option so that a user can go to a particular time period for a selected day.

This whole application can be further improved in terms of usage by providing machine learning based alerts on possible bottlenecks buildups at certain hours and re-routing options thereby helping the authorities to manage the park operations effectively and provide improved user experience to visitors. We plan to bring in this aspect in our future work.

'Does it pay to be green?' revisited: LGM assessment of the relationship between sustainability performance and financial performance

Kelsey Taylor
Ivey Business School, Western University
Email: ktaylor.phd@ivey.ca

ABSTRACT

The question 'does it pay to be green?' has been part of operations management research for decades. As firms face increasing pressure to reduce their social and environmental impacts, managers and researchers alike work to understand the impact of sustainability practices on a firm's bottom line. To add to this on-going dialogue, this paper uses a latent growth modelling approach with longitudinal sustainability performance data to investigate the relationship between changes in sustainability performance and financial performance over time. This paper illuminates areas for future research on the relative financial returns of different types of sustainability investments.

KEYWORDS: sustainability, social performance, environmental performance, financial performance, latent growth modelling

INTRODUCTION

In 1995, Hart asked if the way a firm interacts with the natural world could be a source of competitive advantage? This represented an extension of Barney's Resource-Based View of the firm (RBV) by incorporating the importance of the external environment and sustainability practices in the development of firm capabilities (Hart, 1995). This natural resource-based view (NRBV) proposes that different sustainability measures, like pollution prevention, can lead to sustained competitive advantage in the presence of particular firm capabilities that support their successful implementation. This proposition brought with it a slew of empirical research attempting to understand the relationship between a firm's environmental performance and its financial performance (King and Lenox, 2002; Mitra and Datta, 2014; Sharma and Vredenburg, 1998). More recently, this discussion has expanded to include a firm's social performance (Lu et al., 2013; Barnett and Salomon, 2006), asking 'does it pay to be good?' (Javed et al., 2016) in addition to 'does it pay to be green?'.

All of the above papers suggest that the benefits associated with sustainability policies extend beyond the expected sustainability outcomes like less waste-to-landfill or reduced employee turnover. Yet, these studies provide limited insight into how sustainable this enhanced competitive performance is over the long-term. While it is clear from existing that there is an association between exemplary sustainability performance and strong financial performance, there is limited research on the association between the change trajectories of environmental and/or social performance and financial performance over an extended period of time (King and Lenox, 2002; Liao et al., 2018; Sharma and Vredenburg, 1998; Xiong et al., 2016), leading to calls for more research using longitudinal data (Longoni and Cagliano, 2015; Mitra and Datta, 2014; Russo and Fouts, 1997). To truly understand the impact of sustainability performance improvements, research must examine how long the performance benefits associated with sustainable practices can be maintained. Can a firm improve their sustainability performance

over one period and expect improved financial performance over multiple periods, or is continuous sustainability improvement required for sustained financial gain? Using a latent growth model (LGM), this paper seeks to answer the following question: how do sustained changes in a firm's sustainability performance over time affect the trajectory of its financial performance?

I will begin by summarizing existing work on the resource-based view of the firm and how it has been applied in the context of sustainable operations. Next, I will explain my research methodology and data sources. Finally, I will summarize the results of my analysis, limitations and conclusions.

RESOURCE-BASED VIEW

The resource-based view, as originally theorized by Barney (1991) argued that firm resources that are valuable, inimitable, rare and not easily substitutable can lead to sustained competitive advantage for that firm. Resources in this context refer not only to physical goods, but also intangible resources like skills, knowledge and relationships. This stream of research has been criticized for its frequent failure to differentiate between capabilities and resources (Hitt et al., 2016). Capabilities are defined in the literature as 'the actions through which resources are used and that firms engage in to get something done and accomplish their objectives' (Branco and Rodrigues, 2006, p. 116). Some of these concerns were addressed successfully by Sirmon et al. (2007) in their theory of dynamic capabilities. This theory posits that firms bundle their resources to create particular capabilities, and that it is those capabilities that are leveraged to create sustainable competitive advantage (Sirmon et al., 2007).

In order to successfully implement a particular sustainability practice a firm needs to deploy particular skills. These skills may themselves be a source of competitive advantage for the firm. In his explanation of the 'natural-resource-based view of the firm', Hart (1995) explains the link between different sustainability practices and competitive performance by comparing and contrasting pollution control and pollution prevention. Pollution control, as an 'end-of-pipe' solution', traps and filters emissions immediately prior to their release into the environment, without requiring any changes to the plant's existing processes. Pollution prevention, on the other hand, Hart describes as being 'analogous to total quality management (TQM)' (1995, p. 992) in that it requires higher level capabilities like effective employee engagement and continuous improvement that can have spillover effects like cost reduction. In his work, Hart suggests that pollution prevention practices are associated with process management capabilities that may provide firms with sustained competitive advantage. Pollution control, however, does not involve the development or deployment of these capabilities.

These claims were supported by King and Lenox (2002), which found an association between financial performance and waste prevention, but not waste treatment or transfer. Similarly, Klassen and Vereecke (2012) describe three 'social management capabilities' that have clear implications for competitive performance: monitoring, collaboration and innovation. For example, a firm will need to have strong collaboration capabilities to ensure that sustainability guidelines are implemented successfully across the supply chain, and supply chain collaboration has been demonstrated to have benefits that extend far beyond social sustainability performance (Raskovic and Morec, 2013; Zu and Kaynak, 2012). In this way, the development of social management capabilities may contribute to sustained competitive advantage.

Upon publication, Barney's work had immediate relevance to the issue of corporate sustainability performance through his inclusion of a positive stakeholder reputation in his discussion of potentially beneficial firm resources (Barney, 1991). As stakeholders are increasingly holding firms to account for the environmental and social impacts of their

operations, reputations are becoming a more important source of risk (O'Callaghan, 2007), as well as advantage (Russo and Fouts, 1997). Russo and Fouts (1997) provide several examples of firms like Procter & Gamble who link their reputations for strong environmental performance to their profitability. Strong sustainability performance can also improve the firms' reputation in the eyes of its own employees, increasing employee morale and subsequently performance (Branco and Rodrigues, 2006). Together, this literature suggests that a firm's ability to successfully manage its sustainability performance and image can have important implications for its future competitiveness and profitability.

This paper builds on this existing work by assessing how changes to a firm's social and environmental performance over time may be associated with changes to a firm's financial performance over several years. Based on the literature described, I hypothesize:

> ***Hypothesis 1 (H1)***: The rate of improvement in firm environmental performance is positively associated with the rate of change in firm financial performance.
>
> ***Hypothesis 2 (H2)***: The rate of improvement in firm social performance is positively associated with the rate of change in firm financial performance.

RESEARCH DESIGN

Though there is a substantial set of empirical studies that indicate a link between sustainability performance, especially environmental performance, and financial performance, there are fewer that provide insight to how these relationships hold over time (see Sharma and Vredenburg (1998); Liao et al. (2018); Xiong et al. (2016)). To address calls for more longitudinal research on the link between sustainability performance and financial performance (Longoni and Cagliano, 2015) this paper will use a latent growth model to assess the association between the change trajectories of a firm's sustainability performance and financial performance over a six-year period. The theoretical model being evaluated in this paper is summarized in Figure 1.

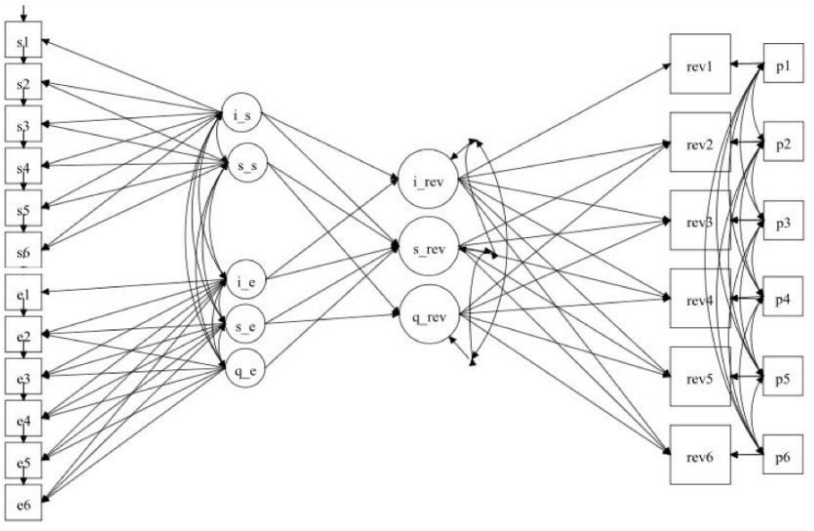

Figure 1: Theoretical model [e = Environmental Score, s = Social Score, rev = Revenue, p = Number of employees, I_x = Intercept of growth curve for variable X, S_x = Slope of growth curve for variable X, Q_x = quadratic term of growth curve for variable X, Numbers 1-6 represent time period 1-6]

One advantage of LGM over methods like fixed-effect regression is that it estimates an independent intercept and growth curve for each observational unit; in the case of this paper, firms. Using these individual growth curves and estimates, two latent factors are estimated, one representing the sample intercept and one representing the sample slope. These latent factors can then be included as predictors of both the initial state and change trajectory of a dependent variable (Lance et al., 2000).

Latent growth models are a well-accepted method for assessing change in particular characteristics over time, both within and between individuals (Lance et al., 2000). As Ketokivi and McIntosh explain, commonly-used methods like fixed-effect regressions can effectively capture variance of a variable within an observational unit over time, but this is not the same as capturing change over multiple periods of time (2017, p. 9). Though this method is most commonly used in human development and other social science literature (Barnes et al., 2000; McArdle and Epstein, 1987), there are no published examples of its use within the OM literature (Ketokivi and McIntosh, 2017). As this paper seeks to understand how the rate of change in sustainability performance relates to the rate of change in financial performance, LGM is an appropriate method of analysis.

DATA SOURCE & SAMPLE

All data used in this study was retrieved from Thomson Reuters ASSET4 database. This dataset, which covers nearly 7,500 public firms, gathers data from firms' annual reports, company websites, news and other sources on over 400 ESG indicators (Thomson Reuters, 2017). These indicators are then collapsed into ten categories, each either classified as environmental, social or governance-related, which are then combined into the total ESG score. Given that this paper aims to investigate the impacts of environmental performance and social performance on financial performance separately, the individual environmental and social scores are used. Each firm's environmental or social score is the weighted sum of all relevant indicator scores in that category, where each indicator score represents the firm's percentile rank compared to other firms in the database (Thomson Reuters, 2017). While the average and standard deviation of the percentile rank scores for the entire dataset are not informative, they provide useful information in this context to frame how the performance of firms in the sample compare to all other firms for which data is available.

The sample for this study is composed of a series firms who appeared on the NASDAQ 100 and/or S&P 500. Initially, data for 521 firms was extracted, though due to data availability issues, the final sample comprises only 471 firms. To represent environmental and social performance, each firm's environmental score and social score was extracted in its final firm from the ASSET4 database. Financial performance is measured using the firm's pre-tax revenue for each period. The number of employees for each firm at each time period was included to control for firm size, which is an accepted practice in the literature (Ambulkar et al., 2015; Wagner and Krause, 2009). Descriptive statistics for the sample can be found in Table 1. Data included in the analysis cover the years 2011 to 2015.

ANALYSIS

An important prerequisite of latent growth modelling is ensuring that the operationalization of the constructs remain valid over time (Lance et al., 2000). Fortunately, given the data used in this paper and the act that all variables included in the model are either directly observed, or compiled in advance at the data source, measurement invariance is not an important concern.

The analysis, which was conducted using Mplus 7 (Muthen & Muthen, 2012) required two stages. First, the appropriate functional form of the growth curve was determined for each variable used in the model. For each variable, the fit of the following types of growth curves were assessed: linear, non-linear, quadratic, exponential and various piecewise models. This was done by constraining the factor loadings of each observational period for each variable to a particular value (e.g., t1=0, t2=1, t3=2 for a linear growth model). By constraining the loading of the first time period for each variable to 0, the intercept of each variable can be interpreted as the initial value of the measured variable (Lance et al., 2000). The relative fit of each potential growth curve was compared using a series of chi-square difference tests for nested models and comparing fit indices when chi-square difference tests were not relevant. As a result of this stage, environmental performance and revenue were modelled using quadratic growth curves, and social performance was modelled using a linear growth curve.

Second, using the appropriate functional firm for each growth curve as established in the first stage, the theoretical model was tested in accordance with Figure 1.

Table 1. Descriptive Statistics

Variable	Period	N	Mean	SD	Min	Max
Environmental Score	1	451	55.6	32.0	9.1	95.0
	2	456	58.6	31.6	8.8	94.7
	3	457	59.7	30.1	8.3	94.2
	4	464	60.2	30.5	8.7	94.5
	5	464	61.3	29.9	8.4	94.7
	6	458	66.9	28.2	9.7	95.1
Social Score	1	451	55.5	29.9	9.1	95.0
	2	456	58.5	28.2	8.8	94.7
	3	457	59.6	32.0	8.3	94.2
	4	464	60.0	31.6	8.7	94.4
	5	464	61.2	30.1	8.4	94.7
	6	458	66.7	30.5	9.7	95.1
Number of Employees	1	455	47727.3	118095.4	79	2100000
	2	462	49077	122161.1	80	2200000
	3	460	50721.4	123487.8	79	2200000
	4	453	51749.5	124240.9	81	2200000
	5	453	52787.4	124471.8	83	2200000
	6	449	55508.9	130718.1	93	2300000
Revenue	1	462	2565136	4659973	-1234728	42541000
	2	464	2820653	5458156	-4842000	58215000
	3	466	2769511	6063005	-29768000	64043000
	4	466	3066235	5808041	-3282000	50291000
	5	467	3081868	5553587	-6618921	53867000
	6	463	2759704	6527230	-27956000	73248000

RESULTS

Before running the analysis, correlations between all variables were calculated. As expected, correlations between repeated measure of each variable over multiple time periods is high. Referring back to the descriptive statistics presented in Table 1, all variables show a general increasing trend over the duration of the measurement period.

To test the hypotheses, a single model was run that connected the slopes and intercepts of each firm's environmental and social performance scores to the slope of its financial performance. Within each firm, the intercept and slope were permitted to covary. To control for the effect of firm size on revenue, each period's revenue was regressed on the number of employees at the firm during that period. The number of employees was a statistically significant predictor of revenue at each period of analysis.

A term was also included that linked the intercept of each firm's environmental and social performance to the intercept of its financial performance to assess if these findings agree with existing work about the association between sustainability performance and financial performance (Esteban-Sanchez et al., 2017; Javed et al., 2016; King and Lenox, 2002; Mitra and Datta, 2014; Sharma and Vredenburg, 1998; Xiong et al., 2016).

The results of the above analysis are presented in Table 2. As shown in the table, the fit indices for the structural model are quite poor. Though the CFI value (0.928) is satisfactory according to some guidelines, some more stringent guidelines suggest a value greater than .95 to claim acceptable fit (Schreiber et al., 2006). The chi-square value and RMSEA both suggest a poor fit. Several alternative specifications were attempted, none of which yielded a significant improvement in the model fit. Despite the poor fit of the model, I chose to move forward with the interpretation of the coefficients.

Table 2 indicates that none of the hypothesized relationships were found to be highly significant, though there was a marginally significant relationship between the quadratic term of the environmental growth curve and the slope of revenue.

Table 2. LGM Results

	Coefficients	**p-value**
I_rev		
I_e	0.595 (.151)	0.000
I_s	-.203 (.173)	0.241
S_rev		
S_e	.504 (.367)	0.170
S_s	-1.535 (1.320)	0.245
I_e	-.045 (.111)	0.688
I_s	0.046 (.110)	0.674
Q_e	2.435 (1.444)	0.092
Q_rev		
S_e	-.022 (.049)	0.656

Hypothesis 1 predicted that there would be a significant and positive association between the slope of a firm's environmental performance over time and its financial performance. This relationship was found to be positive but insignificant (p=.170). However, the quadratic growth term associated with environmental performance was found to have a marginally significant positive effect on the slope of financial performance (p=.092). Together, these findings suggest that there may be a marginally significant, positive, non-linear relationship between a firm's environmental performance change trajectory and their revenue growth trajectory over time such that firms with a greater rate of improvement in their environmental score may also present a greater rate of improvement in their financial performance. A plot of this relationship can be seen in Figure 2.

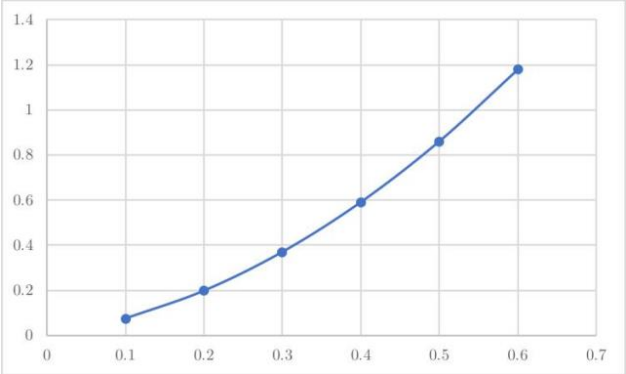

Figure 2. Predicted values of revenue slope by environmental slope

With respect to Hypothesis 2, the results are less ambiguous in their failure to support the hypothesis. The results demonstrate a negative relationship between improvement in social performance and improvement in financial performance, though the relationship is not statistically significant (p=.245).

To assess the presence of a positive association between sustainability performance and financial performance established in existing literature, I regressed the intercept of revenue on the intercept for environmental scores and social scores. This yielded a statistically significant positive relationship between the environmental score intercept and revenue intercept (p<.000). Practically, this means that higher initial environmental performance was associated with higher initial revenue performance. This echoes existing literature that indicates a positive relationship between environmental performance and financial performance (Russo and Fouts, 1997). The relationship between initial social performance and initial revenue, however, was not found to be significant (p=.241), contradicting work that suggests a link between corporate social performance and profitability (Esteban-Sanchez et al., 2017).

To test the robustness of these results and examine the usefulness of this analysis in making causal claims about the relationship between sustainability and financial performance, I conducted an initial analysis using lagged dependent variables. In this model, the change

trajectory from period 1 to period 4 for both environmental and social performance were used to predict the change trajectory from period 3 to period 6 for revenue. These results are presented in Table 3. The fit of the lagged model is significantly better than the fit of the original model, with each measure of fit falling within the acceptable values outlined in Schreiber et al. (2006). Comparing the lagged model to the original model, the quadratic term of the environmental growth curve is no longer marginally significant. This lack of significance in the lagged model casts doubt on any interpretation of the previous results that suggests a causal relationship between environmental performance and financial performance. It supports earlier findings of no relationship between social performance and financial performance.

LIMITATIONS AND CONCLUSIONS

One important limitation of this analysis is the lack of support for measurement invariance (Vandenberg and Lance, 2000). Although the environmental and social performance scores used in this analysis are themselves latent constructs encompassing many dimensions of sustainability performance, they were extracted from the ASSET 4 dataset in their compiled form, prohibiting the analysis of measurement invariance. However, ASSET4 data is being used more frequently within the literature in recent years (Chopra and Wu, 2016; Dell'Atti et al., 2017; Esteban-Sanchez et al., 2017) and has been shown to converge well with other commonly-used measures of environmental performance (Semenova and Hassel, 2015), supporting the validity of their methodology.

An additional limitation of the analysis is the use of a single indicator as a measure of financial performance. Though revenue performance is often used as a measure of financial performance, it is often included with other indicators in more comprehensive latent construct (Blome et al., 2014; Xiong et al., 2016). For example, some papers use both accounting-based measures and market-based measures to present a more comprehensive picture of firm financial performance (Esteban-Sanchez et al., 2017; Wang and Sarkis, 2017). This analysis would have been strengthened by the inclusion of additional financial performance indicators.

Future studies can use a similar LGM approach to assess how changes in sustainability performance affect operating performance over time. The inclusion of a latent construct representing the change in operating performance could provide more insight into the impacts of improving sustainability performance that may not be easily captured by market-based performance measures, like improvements to operating margins or improved ROA.

Though these results should be interpreted carefully due to model misfit, the results suggest an interesting discrepancy between the returns associated with investments in social performance relative to environmental performance. Contrary to the hypotheses, a quicker rate of improvement in social sustainability was associated with a decrease in the rate of improvement of financial performance. While these negative coefficients may be solely due to model misspecification, they present an interesting research question: what is the difference, if any, in firm returns on investments in environmental performance and social performance? Pullman et al. (2009) examine the impacts of social and environmental practices on cost performance via environmental and quality performance, but only a small subset of sustainability practices is included in their analysis. Future research can expand on their work to examine the subset of a wider set of environmental and social sustainability practices and their change over time as a predictor of the growth trajectory of other dimensions of performance (e.g., operational, financial) to highlight which specific sustainability practices may provide the greatest performance returns over time.
